Neuroendocrine differentiation for most of the clinicians is associated with progression of prostate cancer to castrate – resistant disease.

NEUROENDOCRINE CELLS IN THE NORMAL PROSTATE

Neuroendocrine cells are found in many types of tissues, including in the normal prostate [4]. This cells secrete neuropeptides such as: serotonin, histamine, chromogranin A, calcitonin, bombesin, neuropeptide Y, vasoactive intestinal peptide, adrenomodulin [5],[6],[7],[8] and also growth factors (VEGF) [9]. The principal role is to maintain local homeostasis of the surrounding epithelial cells. Some of these neuropeptides have been found in seminal fluid, raising the idea that they may regulate sperm function [10][11].

Studies shows that neuroendocrine cells are present in all anatomic zones of the prostate and comprise less then 1% of benign prostatic glandular epithelium [12].

Neuroendocrine cells cannot be recognized on routine Hematoxilyn-Eosine staining. Ussualy this cells are found using immunohistochemistry with specific markers: chromogranin, synaptophysin, neuron specific enolase and CD 56 [13][14][15][16]. Other neuroendocrine cells markers reported in literature but not ussualy used in clinical practice include: cytochrome b561 [17], synaptic vesicle protein 2 [18][19], vesicular monoamine transporters [20].

NEUROENDOCRINE DIFFERENTIATION IN PROSTATE CANCER

Neuroendocrine prostatic carcinomas are often diagnosed on primary prostate needle biopsy with negative or low PSA level.

Neuroendocrine carcinoma of the prostate may be linked to resistance to androgen receptor signaling inhibition. Some prostatic tumors such as carcinoid tumor and small cell carcinomas are entirely composed by this type of cells with neuroendocrine differentiation. These tumors are aggressive and often present locally advanced or metastatic diseases with poor survival prognosis [21]. In general, these cells are negative for androgen receptor and PSA. Hormonal therapy is not effective while chemotherapy may have some value [22].

More frequently, prostatic tumors are composed by conventional adenocarcinoma with a small component of cells with neuroendocrine differentiation.

The neuroendocrine cells are indistinguishable from the normal adenocarcinoma cells on Hematoxilin-Eosine stained section under light microscope, and can be identified only by immunohistochemical stained using specific markers. Chromogranin A is the most used marker in clinical practice and is considered to be sensitive and specific [23].

Prostatic tumors with high grade or high stage and particularly in hormonal treated or hormone-refractory tumors, neuroendocrine differentiation is increased [24][25][26]. Also the level of serum chromogranin A are increased and is associated with tumor resistence to hormonal therapy [27]. In patients with hormone-refractory tumors, elevated serum chromogranin A level is predictor of poor prognosis, independent of PSA level [28].

NEUROENDOCRINE DIFFERENTIATION AND HORMONE-REFRACTORY PROSTATE CANCER

If the local curative treatments (radical prostatectomy, brachytherapy, radiotherapy) are no longer indicate for the patients with prostate cancer, androgen deprivation therapy is an effective therapy with significant symptomatic relief, suggesting that tumor growth is dependent on androgen receptors signaling. It is known that prostatic stromal cells support survival and proliferation of epithelial cells (paracrine secretion), that’s why, it is possible that neuroendocrine cells (who do not express androgen receptors and so are resistant to androgen deprivation) being capable to secrete neuropeptides and cytokines and so stimulate proliferation of adenocarcinomas cells. This situation suggest that androgen deprivation generally works, but eventually fails because neuroendocrine cells gradually substitute the function of stromal cells and so continued to stimulate the proliferation of prostate cancer cells.

Antibiotic resistant urinary tract infections in an urology ward

A. Rădulescu[1], Victor Mădan[1,2], A. Aungurenci[1], Ovidiu Bratu[1,2], C. Farcaş[1,2], Marius Dinu[1], Dan Mischianu[1,2]

Abstract: Introduction: UTI (urinary tract infections) represent a central pathology for a urological service. Antibiotic resistance is growing at a steady and alarming rate worldwide and especially in Romania.

Method and materials: We have analyzed all the patients that were admitted to our clinic for continuous hospitalization between January 2015 and October 2015. All patients undergone urine culture and all cultures positive had an antibiogram worked up. We have selected all patients that had antibiotic resistance to at least an antibiotic.

Results: From 1745 patients admitted for continuous hospitalization, we had 180 positive urine cultures at admission from which 125 had at least an antibiotic resistance.

Conclusions: Antibiotic resistance is a serious phenomenon, with potential lethal complications, which we encounter daily in urological practice

INTRODUCTION

Uncomplicated UTI are probably the most common urological condition. It is estimated that at least 1 out of 3 females will develop an UTI during their lifetime. UTI frequency at young females is associated with sexual intercourse. When urological malformations, pregnancy, menopause, urolithiasis occur conditions for recurrence of the disease are met. Recurrences are defined as at least 2 episodes of UTI in 6 months or 3 episodes a year.

Male patients develop UTI due to different mechanisms and at an elderly age. The most common mechanism that facilitates the development of UTI in men is bladder outlet obstruction caused mainly by prostatic enlargement.

UTI are caused mainly by Gram negative *enterobacteriacea*. Escherichia Coli is the cause for about 80-90 % of community acquired UTI's. In healthcare related infections E. Coli is still the leading cause but with a more modest percentage. Other pathogens that cause UTI are: Proteus mirabilis, Enterococous, Klebsiella pneumonie, Pseudomonas aeruginosa.

METHOD AND MATERIALS

Between January and October 2015, 1745 patients were admitted for continuous hospitalization in our Clinic. At admission all of these patients had their urine sent for culture.

The urine culture was tested for antibiotic response for the following antibiotics:

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest
[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

Trimethoprime-sulfamethoxazole, cefuroxime, cefotaxime, ceftriaxone, ciprofloxacine, ofloxacine, levofloxacine, gentamicine, ampiciline, oral penicillin, nitrofurantoine, imipenemcilastatin, ertapenem, meropenem and tigeciclin.

We had 180 positive urine cultures from which 125 were antibiotic resistant at at least one tested antibiotic.

We have analyzed the relationship between the germ and antibiotic resistance and also the sex and age of patients.

RESULTS

We had 180 positive urine cultures representing 10.31% out of all patients. 7.16% of all patients had at least one antibiotic resistance. 70% of the patients with positive urine cultures had at least one resistance.

Out of the 180 patients 104 were females (57,7%) and 76 were males (42,3%). Resistance was encountered in 56 females (44,8%) and 69 male patients (55,2%)

Out of all UTI's we had 143 E. Coli cases (79%), 25 Klebsiella pneumoniae (13,88%), 12 Proteus mirabilis (6,66%), 8 Enterococus (4,44%) faecalis and 2 cases with Pseudomonas aeruginosa (1,11%).

In the antibiotic resistant group we encountered the following bacterial involvement: 88 patients had E. coli, 19 had Klebsiella pneumoniae, 10 had Proteus mirabilis, 6 had Enterococus faecalis and 2 had Pseudomonas aeruginosa.

The decreasing percentage of antibiotic resistance was the following: Psedomonas aeruginosa cases had 100% resistance at at least one antibiotic, 83% of Proteus mirabilis cases had resistance, 76% of Klebsiella cases had resistance, 75% of Enterococus faecalis had resistance while the least resistant germ was E. Coli with 61,53%.

There were no significant differences between sexes except the fact that all the 2 cases with Pseudomonas aeruginosa were registered at male patients with long time users of indwelling ureteral catheters.

Regarding antibiotic resistance we had only 2 cases(1 case with Pseudomonas and 1 case with Klebsiella) which had no sensibility to any of the tested antibiotics. The strongest resistance was registered to ampicllin meaning that 115 (92%) cases with resistance had no sensibility to the drug. Resistance to penicillin was counted at 97 (77%). Third highest resistance was encountered to Thimetoprim with 90 patients (72%). The lowest resistance was registered for imipenem cilastatin, ertapenem, meropenem and tigeciclin. With only 2 cases (1,6%). Levofloxacin had also low resistance with 25 cases meaning 20%.

CONCLUSIONS

Antibiotic resistance is real threat to the general health of humanity, being more and more encountered especially in hospital related infections but also in community acquired infections. UTIs make no exceptions. Romania is especially at high risk with reported resistance to quinolones exceeding 30%.

The data we obtained from patients admitted for continuous hospitalization in our Clinic is similar to data in international literature reports concerning antibiotic resistance. It is important to realize the fact that urological patients are at high risk of developing antibiotic resistant infections due to the age profile, the pathology and the increasing number of indwelling catheters.

Complications of radical retropubic prostatectomy – our experience

Ovidiu Bratu[1,2], D. Spînu[1,2], I. Oprea[1], R. Popescu[1], D. Marcu[1], C. Farcaș[1,2], Marius Dinu[1], Dan Mischianu[1,2]

Abstract: Introduction: Radical retropubic prostatectomy represents in its various forms (open, laparoscopic and robotic) the "gold standard" treatment for adenocarcinoma of the prostate. Unfortunately like al treatment solutions it has its shortcomings.

Retropubic radical prostatectomy, external beam radiation therapy and brachytherapy are the curative options.

Materials and Method: The experience of Clinic of Urology from Central Military Hospital representing more than 100 cases was analyzed . Classical open retropubic prostatectomy was performed in all cases.

We focused in this paper on intraoperative complications and also precocious and late postoperative complications.

Results: Our results are matching the other centers in terms of intraoperative complications (blood loss), early postoperative complications (hematuria, urinary tract infection, lymphatic drainage) or late postoperative complications (erectile dysfunction and urinary incontinence). However none of these complications are to be underestimated

Conclusions: The limits of this intervention can be pushed a litle bit further, in our opinion the age factor is a relative one, some of these patients having a longer than 10 years life expectancy. It provides good oncological outcome with manageable complications most of the times.

Keywords: radical retropubic prostatectomy, complications, nerve sparing

INTRODUCTION

Prostate cancer is nowadays the second most frequent neoplasia in men. Most probably the reason for this frequency is the presence of PSA as a valuable diagnosis tool and also the existence of the guidelines.

Also the very aggressive policy of controls for all men after 50-55 years has begun to show its results. Although radical prostatectomy, radiotherapy and brachytherapy are almost equal in terms of oncological results, in psychological, financial, and why not life quality radical prostatectomy is represented better.

MATERIALS AND METHOD

We have analyzed our experience at the Central Military Hospital regarding radical prostatectomy between January 2009 and February 2015. Our surgical teams carried on during these period more

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest
[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

than one hundred radical prostatectomies for patients with localized or advanced prostate cancer. This paper focuses on intra and post - operative complications we encountered[1,2].

Patients mean age was 63.09 years ranging between 51 to 78 years of age. We haven't taken into consideration the general life expectancy for men in Romania, moreover the general biologic status was considered as inclusion criteria.

Major diagnosis criteria for prostate adenocarcinoma were: anamnesis, total PSA and free PSA levels, digital rectal examination and transrectal ultrasonography, which was usually performed when prostatic biopsies were obtained[3,4].

Medium prostatic volume of 45 cc without taking into consideration patients that prior have benefited of endoscopic surgery.

PSA levels varied between 0.5 ng/ml and 24 ng/ml. Two cases presented with PSA levels above 20 ng/ml. Those two patients were classified postoperative as pT3b – locally advanced.

Mean Gleason score, which is an important prognosis factor, was between 5-7 at 84 patients. Low risk prostate adenocarcinoma was recorded in six cases, ten patients with Gleason 8 were included in high risk and very high risk groups Patients diagnosed with Gleason 9 score were unsuitable for surgery.

In accordance with European Guidelines surgery was performed at six to eight weeks after the transrectal biopsy and 12 weeks after the transurethral resection of the prostate in order to to reduce the prostatic inflammation. General anesthesia was chosen for all patients.

Pelvic lymph node dissection was performed at almost all patients. We used extended lymph node dissection when patients were included in high or very high risk groups.

Urethro-vesical anastomosis was realized using four to eight resorbable sutures excepting six cases when no sutures could be placed due to the short urethra left after the prostatic excision. Those six cases were managed by gentle traction of the urethro-vesical catheter and maintaining the catheter for 14 days compared to 7 to 10 days as we did on the other cases.

RESULTS

The most redutable intraopearatory complication we encountered was blood loss which ranged between 400 milliliters and 2500 milliliters. Twenty - two patients needed intraoperatory blood transfusions.

Early complications included: gross hematuria (eight cases) which spontaneously remitted in 24 to 48 hours, wound infection (six cases), prolonged lymphatic pelvic drainage (sixteen cases), urinary tract infection (twenty cases), pulmonary embolism with subsequent death of the patient (one case).

Eighteen patients developed moderate or severe LUTS caused by bladder neck sclerosis or urethral stricture which was managed trough endoscopical procedures in the first year post-op. Four cases developed urinary fistula during the first 72 hours after prostatectomy three needing surgery in order to perform a new urethro-vesical anastomosis and one being resolved by placing a gentle traction on the urethro-vesical catheter for 24 hours.

Late complications recorded were urinary incontinence and erectile dysfunction. Following data were analyzed at one year after the surgery, only 78 patients being included in the evaluation. Urinary incontinence was evaluated by the number of pads used by the patient.

Almost 80% confirmed that they do not use any incontinence pads. Ten patients use only one pad a day and lose urine only when changing positions or when sneezing or coughing. Three patients affirmed moderate urinary incontinence using 2-3 pads a day[5].

We used a similar technique like the TOT used for women to place a suburethral transobturatory mesh for eleven ot if the thirteen patients with urinary incontinence with very good results and lack of symptoms in nine cases.

Using Walsh technique neurovascular bundles were spared in 62 patients. Erectile function, a very important part in quality of life was assessed using anamnesis and standardized questionnaires. 68.42%

(26 out of 38 patients) of the patients with surgical bilateral neurovascular bundles preservation affirmed satisfactory erections while only 33% (eight out of 24 patients) with unilateral bundle preservation affirmed satisfactory errection[6].

In sixteen cases due to oncological reasons or intraoperative bleeding neurovascular bundles were not preserved. All patients that benefited from the nerve sparing technique surgery were set on low dose daily 5 PDE inhibitors.

CONCLUSIONS

Radical prostatectomy is the standard treatment for localized and in some cases of locally advanced disease. We consider biologic status to be a more reliable indicator than age alone. That being said we consider far better to evaluate the patient before judging only the age.

Surprisingly one of the most bothering complications we encountered was bladder neck sclerosis; in this case one of the patients had undergone endoscopic surgery for three consecutive times. One of the hypotheses is the using of tension on the urethro-vesical catheter consequent bladder neck ischemia and in a secondary time sclerosis. This was not the case of this patient.

Intraoperative bleeding remains one of the most serious problems also because of the underlying co morbidities which may be aggravated during surgery.

Incontinence is a very bothersome late complication. Psychologically it has a great impact on the patient quality of life; actually along with erectile dysfunction those two are considered to be the highest burden from the patient's point of view. Still the existence of TOT like procedure for men offers an efficient solution to this problem.

Scintigraphic evaluation of the kidney

Iulia A. Chiriac[1], Raluca M. Mititelu[1], Cătălin Mazilu[1], Olga Niculescu[1], Mihaela G. Lepuș[1]

Abstract: *There are more than one technique used to evaluate the kidney, besides the standard ultrasound, computed tomography (CT), and magnetic resonance imaging (MRI), there is also renal scintigraphy. The renal nuclear medicine procedures are grouped as in vitro (urine counting wells, basic probe detectors for clearance studies) and in vivo procedures (static and/or dynamic examinations done with planar gamma cameras, and single-photon emission computed tomography (SPECT) to determine kidney parameters or for cortical imaging). Renal scintigraphy has been a useful tool, since the early 1950s, in the diagnosis and management of many pathological changes in the kidney, especially in measuring renal function (e.g. obstructive/nonobstructive uropathies, renal inflammatory diseases, tumours, renal hypertension, and renal transplant viability). [1]*

INTRODUCTION

The radionuclide investigation of the kidney includes detection of renal afflictions and measurements of quantitative indices that estimate the renal perfusion and function. Ultrasound and computed tomography are commonly used for the evaluation of renal structural anatomy, and the role of nuclear renal imaging is more for functional analysis, less in anatomical imaging (e.g. cortical imaging).[1,2]

Renal scintigraphy, also known as a "renal scan" or "renal radionuclide imaging" or “renography” includes various investigations that use different radioisotopes to evaluate renal blood flow, renal split function, and the renal excretion performance of both. It yields specific and often unachievable information by using other imaging procedures. [2]

Clinical indications for renal scintigraphy (adapted from *Nuclear Medicine: The Requisites*, 4th ed)**:** [3-5]

1. Blood flow abnormalities
2. Function quantification (reduced performance of one or both kidneys)
   a. Differential function
   b. Glomerular filtration rate (GFR), effective renal plasma flow (EPRF)
3. Cirrhosis of the kidney(s)
4. Differentiation between a mass lesion and a column of Bertin
5. In infants with abnormalities of the urinary tract to study the urinary flow
6. Obstruction: ureteropelvic junction, ureteral
7. Pyelonephritis: both acute and chronic tubule-interstitial nephritis and parenchymal scarring
8. Renal failure: acute and chronic
9. Renal artery stenosis with/without renovascular hypertension
10. Renal vein thrombosis
11. Surgical:

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

a. performance assessment before operations in the case of chronic diseases (e.g. diabetes)
b. Renal allographs: for clinical monitoring of renal function, transplant rejection or other complications, transplant anastomosis assessment
12. Trauma

PURPOSE

The purpose of this paper is to provide a better understanding about dynamic renal imaging in several kidney pathologies, with an emphasis on obstructive renal pathology and to clarify the meaning of some quantitative parameters used in renal scintigraphy.

MATERIAL AND METHODS

Nuclear renal scans are various, complex and also a subject to institutional preferences, that is why a standardization of the techniques is hard to achieve. All nuclear renal procedures have some basic common conditions that must be taken into account before, during and after patient examination. First of them involves the intravenous bolus injection of a renotrophic radiopharmaceutical (a medicine marked with a radioisotope) that emits a small amount of radioactivity into the patient. Usually, the radiotracer administered to the patient is well tolerated, with no systemic toxic effects. Some mild-moderate allergies or adverse reactions (such as dizziness, headache, metal taste, flushing) are extremely rare reported. The radiation dose is relatively low, less than the standard chest x-ray. The examination is performed with the patient either lying on the examination table, in the supine position, or standing. [3-7]

The pre-scan preparatory measures that are common are hydration, about 30 minutes prior to the actual examination, the patient should drink about 1 litre of fluid, and an empty bladder, the patient should void before examination. [3-7]

It is of great importance that in the last 3-6 months prior to the renal scintigraphy, no high doses of iodine substances to be taken, like x-ray and CT contrast agents, or certain medicines (e.g. Amiodarone) because the results could otherwise be distorted. [3-7]

In general, chronic therapy medications should not be discontinued prior to the exam. For specific problems, specific blood pressure lowering drugs (ACE inhibitors, diuretics) must be mentioned to the nuclear medicine physician as there is a period of drug abstinence in some cases. [3-7]

Different scanning protocols with various radiopharmaceuticals are available for scanning the kidneys. Choosing the right technique and optimal radiopharmaceutical depends on the patients' medical history, clinical setting and indication. [3-5, 8]

Plenty and divers radiopharmaceuticals have been produced in the last 60 years to assess renal function; some are used in laboratory assays by measuring blood samples and determining the renal clearance of the radiopharmaceutical and others for dynamic or static studies with a gamma camera or a SPECT system. The gamma cameras and SPECT systems monitor the passage of radiopharmaceuticals through the kidney and urinary tract by registering and processing of the emitted gamma radiation. [9, 10]

The radionuclide agents usually used for determining renal function and anatomy can be grouped into three main categories [5,8]: those filtered by glomerular filtration, those excreted by tubular secretion via proximal tubule receptor-mediated endocytosis from the glomerular filtrate, and those retained in the renal tubules for long periods, useful for cortical imaging. [8]

The most frequently used radiopharmaceuticals in renal scintigraphy are illustrated in Table 1.

Table 1. Most frequently used renal radiotracers

Glomerular Filtration (GF)	• Tc-99m diethylenetnamine pentaacetic acid (Tc-99m DTPA) • 99mTc-mercaptoacetyltriglycine (Tc-99m MAG3) • I-131/I-123 orthoiodohippurate (OIH)
Tubular Secretion (TS)	• I-131 OIH • Tc-99m MAG3 • Tc-99m ethylenedicisteine (Tc-99m EC)
Tubular Filtration (TF)	• Tc-99m dimercaptosuccinic acid (Tc-99m DMSA) • Tc-99m glucoheptonate (Tc-99m GHA)

Table 2. Renal radiotracers excretion mechanisms (adapted from *Semin NM Apr.92*)

	GF	TS	TF
Tc-99m DTPA	>95%		
Tc-99m MAG3	<5%	95%	
I-131 OIH	20%	80%	
Tc-99m GHA	40%-60%		20%
Tc-99m DMSA	some		60%

There are four important types of renal imaging methods obtained by using a planar gamma-camera or a SPECT system in order to evaluate whether the kidneys are working normally or abnormally:

- Renal perfusion and renal function imaging are dynamic studies with images taken in series, over a period of 30 minutes immediately after the bolus radiotracer injection and determines the blood flow distributed to the kidneys, recognizes a potential narrowing of the renal arteries, and helps in determining the kidneys functioning. [2, 11]

- Diuretic renal scintigraphy is used to detect kidney obstruction. The procedure is similar to the renal perfusion, and seriated images are taken before and after the introduction of a diuretic (in the 15th minute of acquisition) to help urine elimination from the kidneys. [2, 11]

- ACE-inhibitor renal scintigraphy utility is in detecting renovascular hypertension, not renal artery stenosis, by comparing renographic images before and after taking an ACE-inhibitor. [2, 11] It is also a dynamic study and the image acquisition process begins when the radiotracer is injected intravenously in bolus. [3-5, 8, 10]

- Cortical renal scintigraphy is a static study and detects the amount of normal functioning kidney tissue. [2, 11] After the tracer administration, there is a three hour delay before the imaging acquisition can begin. [3-5, 8, 10]

Generally the dynamic renal functional studies are acquired in two parts. The first part evaluates the renal blood flow, which is calculated in the first pass of the radiopharmaceutical bolus through the abdominal aorta and renal arteries. The second part assess the kidney uptake and clearance function over the next 25 to 30 minutes of acquisition. [3-5, 8, 10]

GFR and EPRF are important kidney function markers evaluated by dynamic renal scintigraphy. Normal GFR varies in accordance with age, sex, weight (nutritional status), diet, race, and kidney size, which is proportional to body surface area. [12, 13, 14] The estimated GFR is calculated using these factors and the serum creatinine value, but it is not helpful when there are unilateral changes or when kidney function is very abnormal. Unilateral renal function changes are difficult to identify with other imaging techniques, but easy to determine with camera-based renal scan split functions. The percent differential function (split function) calculates the contribution of each kidney to the renal function and can be applied to GFR or ERPF data. [3-4, 15]

Nuclear techniques are not 100% "accurate" in measuring kidney function (GFR, ERPF), but are superior to investigations based on the serum creatinine value. [3, 14] Using renal scintigraphy patients can be followed over a long period of time, because this technique is highly reproducible in any one patient. [3, 13, 14]

Table 3. Renal radiotracers used for renal function measures
(adapted from *Requisites of Nuclear Medicine 4th ed*)

Effective Renal Plasma Flow (ERPF)	Tc-99m MAG3 I-123 / I-131 OIH H-3 or C-14 paraamino-hippurate (PAH) I-125 or I-131 iodopyracet
Glomerular Filtration Rate (GFR)	Tc-99m DTPA Cr-51 EDTA I-125 diatrizoate I-125 iothalamate C-14 or H-3 inulin In-111 or Yb-169 DTPA Co-57 vitamin B12

The Tc-99m DMSA cortical scan is used to evaluate renal cortical lesions in patients with suspected pyelonephritis, to detect renal scarring in a patient with reflux, and, in some occasions, to differentiate a prominent column of Bertin from a tumorous formation. Renal cortical scintigraphy provides additional information by showing changes and improvements over time, that are impossible to evaluate with conventional structural and anatomical imaging modalities, like ultrasound, CT, and MRI. [3, 13, 14]

RESULTS

The images obtained with the gamma camera should be inspected after acquisition in order to evaluate if the examination was done in proper conditions. After visual inspection the image data is processed and regions of interest (ROIs) are defined over the kidney and surrounding background so that the renogram curves can be generated. [5, 7]

The time-activity curve (TAC) represents a graphic illustration of the renal function and is composed of 3 parts: initial rise, upslope and downslope. The first part reflects the radioactivity that arrives via the renal artery to the kidney. The upslope (ascending limb) reflects kidney uptake before the radiopharmaceutical begins to be excreted by the kidney (the descending limb). The peak time accurately indicates the point at which the extraction and accumulation trend is reversed to the evacuation process. [5, 7]

This curve is important in diuretic renal scintigraphy. Diuresis renography helps to discern between obstructive (calculus) and nonobstructed dilated urinary tract, and in the postsurgical evaluation of the renal system function and urodynamic. Acute obstructive uropathy is a commonly encountered condition. When unilateral obstruction occurs the changes in the measured renal function are a little decrease or imperceptible, but the bilateral form can result in significant kidney function losses. [5, 16]

The radionuclide renogram TAC provides an accurate graphic illustration of the dynamics of urinary excretion. In obstructive uropathy a calculus can give various degrees of hydronephrosis, depending on the site in which it is lodged. In the case of acute obstruction due to a renal calculus, pressures increase fast in the pyelocaliceal system and in the ureters above the point of obstruction. The affected kidney has a characteristic aspect: a dilated urinary tract with a thin cortex, and it shows on the TAC a slow continuous accumulation of tracer in the collecting system, a slow increasing ascending curve with no downslope. In contrast, the opposite kidney, which has a normal function and no obstruction, will show a good uptake and excretion, and the three part TAC. [7, 17]

In some cases the calculus produces a partial obstruction of the urinary excretion pathways. In order to demonstrate this a diuretic like Furosemide is administrated at various times during the course of the renal scan. The decreasing aspect of the curve after the administration of the diuretic indicates an incomplete obstructive pattern (as in Curve 3), and as for the rising curve a complete obstruction (as in Curve 2). [7]

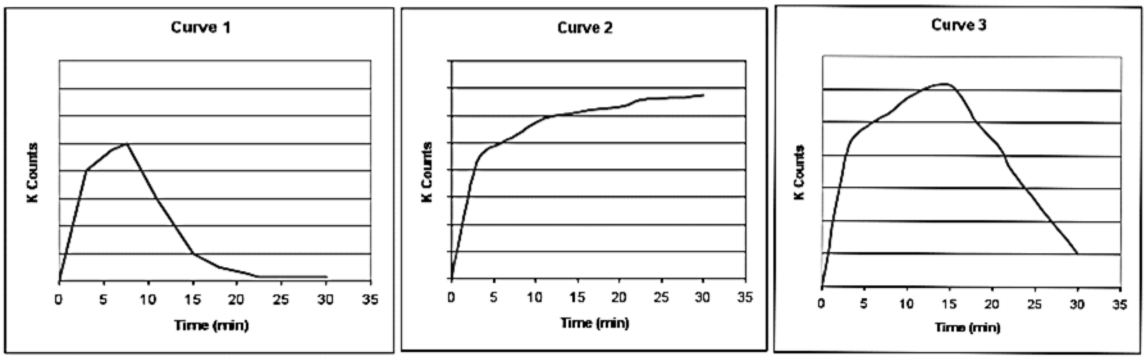
(adapted from *EANM: Dynamic renal imaging in obstructive renal pathology. A Technologist's Guide*)
Curve 1- normal kidney function; Curve 2- complete obstruction; Curve 3 - incomplete obstructive pattern after the administration of Furosemide at minute 15.



QUANTITATIVE INDICES

Renal perfusion is evaluated by visual and quantitative analysis (1- to 3-second images) of the initial bolus as it transits the abdominal aorta and enters the renal arteries (used in renal number anomalies, renal transplant). [10, 11]

Relative Function represents the relative uptake of the radiopharmaceutical for the evaluation of uni-/ bilaterally impaired kidneys. [10] The split function is particularly useful because estimated GFR and serum creatinine may not identify unilateral lesions. [3]

Renal Size. Several chronic renal diseases will result in bilaterally small kidneys, whereas the kidneys may be bilaterally enlarged in early diabetic renal disease, acute interstitial nephritis, HIV nephropathy, and amyloidosis. The resolution of structures of the renal parenchyma with nuclear medicine may not be as clear as with other imaging techniques, such as CT or MRI that is why nuclear renal images are not usually used to differentiate between cysts and tumours. [10, 11, 18]

The time to peak, or T max, refers to the time from radiopharmaceutical intravenous administration to the peak height of the renogram curve. 99mTc-MAG3, 99mTc-DTPA and OIH renograms normally peak by 5 min and drop to half-peak value until the 15th minute after injection; however, in some cases, physiologic retention of the radiotracer in the renal calyces or pelvis can alter the aspect of the TAC in normal kidneys and lead to prolonged values for the time to peak, 20-min/ maximum count ratio, and T½. [8, 10, 19, 20]

Time (mins)

The T½ represents the time is necessary for the radioactivity in the kidney to drop to 50% of the maximum value (time to peak, or T max); this index is important in diuretic renography for patients with suspected urinary tract obstruction. [8, 10, 19]

The 20-min/maximum count ratio is an index of the transit time and a measurement of residual cortical activity, the ratio between the kidney counts at 20 min to the maximum (peak) radioactivity; it is useful in monitoring patients with suspected urinary tract obstruction and for detecting renovascular hypertension. [8, 10, 19]

CONCLUSION

Renal radionuclide studies are versatile procedures and vary depending on institutional preference, clinical setting of the patient and medical indication.

Renal scintigraphy is a complex subject and understanding some basic principles, the use of radiopharmaceuticals available to image the kidney and monitor its function, the quantitative indices that can be generated and protocols can be useful for the physicians specialized in nephrology and urology in evaluating patients with diseases of the urinary tract and renal physiology.

Article received on October 3, 2015 and accepted for publishing on November 18, 2015.

Penile prosthesis – a viable solution for erectile dysfunction refractory to conservative therapy

D. Marcu[1], Ovidiu Bratu[1,2], D. Spînu[1], A. Rădulescu[1], C. Farcaş[1,2], Dan Mischianu[1,2]

Abstract: Introduction: Erectile dysfunction(ED) is a serious condition which can affect men of all ages, with an important impact over the quality of life. When conservative therapy fails, a viable solution is the penile prosthesis implantation (PPI).
Objective: The purpose of this paper is to present data from recent literature regarding the satisfaction rates of men who have undergone penile PPI and as well as the partners satisfaction rates, ease of use, informations regarding long term survival of these prosthesis, postoperative complications and long distance complications, the effectiveness and the way that penile prosthesis have influenced the quality of life of the men who have opted for this solution.
Material and methods: We have analyzed recent long term studies concerning the outcomes of the PPI, studies which were made retrospectively, over a period of time of 10 to 15 years.
Results: Compared with the conservative treatment for ED, the satisfaction rates achieved after penile prosthesis implantation are higher. According to these studies, the overall patient's satisfaction is 70-90%. The difference between patient and their partners' satisfaction rate is negligible, this difference ranging between 2 to 8%. The satisfaction rate regarding the adequate erection for sexual intercourse is 80-90%. The overall satisfaction rates for the malleable prostheses are lower compared with inflatable devices, 30-75%, respectively 75-90% for the inflatable prosthesis. The mechanical and overall survival rates for the malleable prosthesis range between 65-80% at 10 years, and 58-75% for the inflatable devices. Overall ease of use is rated as 78%. Complications after implantation can be encountered in less than 5% of cases and infections in less than 2%. The likelihood of continued use is higher in the group of the patients with the inflatable prosthesis compared with the malleable ones 70-80%, respectively 50-60%. Up to 85-90% of patients with inflatable prosthesis would recommend them.
Conclusions: PPI is a high effective treatment for erectile dysfunction, refractory to pharmacological treatment. The inflatable penile prosthesis (IPP) provides more overall satisfaction than the malleable ones. The patients with IPP are more likely to continue using their devices than those with the malleable prosthesis. PPI improves significantly the quality of life for patients with erectile dysfunction.

INTRODUCTION

Erectile dysfunction is defined as the inability to obtain and maintain an erection with sufficient penis rigidity, adequate for successful sexual contact. Although ED decreases significantly the quality of life for both men and their partners, in many countries

---

[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

ED is understated because of cultural aspects.

ED can affect men of all ages, but as life expectancy continues to increase, so does its prevalence. It is estimated that the prevalence of ED in men over the age of 50 years is higher than 50 percent, and this prevalence grows as the age increases. This condition is not exclusively encountered in men over the age of 50. It is estimated 3-5 percent of young men with ages between 15 and 25 years may suffer from this condition and 7 to 10 percent of those with ages between 25-45 [1].

Despite initial beliefs that the most common cause for ED was the psychological factor, especially in young men, it is now proven that organic causes are responsible for 70 to 90 % of ED. There are several proven pathologies proven in ED [2]:

a) Diabetes Mellitus-is a frequent cause of ED. Men with DM compared with general population may have ED at an earlier age. The prevalence of ED in the population of men with DM can be as high as 70-80%. The peripheral polineuropathy, microangiopathy and arterial insufficiency encountered in DM evolution can explain the earlier age of ED appearance and a higher prevalence than individuals without DM [3].

b) Vascular causes-atherosclerosis plays an important role in ED physiopathology. The presence of aortic or iliac atheromatosis can decrease the blood inflow, thus explaining the ED prevalence of up to 50 % in patients with atheromatosis. Another vascular cause may be the increased venous outflow, which depends on the trabecular smooth muscle relaxation and on the erectile tissue's capacity of expandability.

c) Iatrogenic causes responsible for ED- renal transplantation, aortic or peripheral surgery, abdominal perineal resection of the rectum, perineal irradiation, cystoprostatectomy or radical prostatectomy (RP). Erectile dysfunction secondary to cystoprostatectomy and radical prostatectomy may be encountered in up to 80% of cases. Since the nerve sparing RP was introduced by Walsh over years ago, the incidence of ED was decreased to 40-60% [4]. The incidence of ED post RP depends on patient age, comorbidities, preoperative potency status, type of surgery, surgical technique (open, laparoscopic or robot assisted RP), surgical experience, extensive nerve sparing (unilateral or bilateral) [5]. Although some patients believe that radiotherapy may be associated with a lower risk of ED, it has been proven that ED may be encountered in 20-80% of patient who has undergone radiotherapy. Studies have shown that the incidence of cavernosal fibrosis and ED are similar between RP and radiotherapy [6,7].

d) Trauma – pelvic fractures may affect the internal pudendal or common penile artery or the neurovascular bundle.

e) Endocrinological causes such as: hypogonadotripic hypogonadism, hypergonadotropic hypogonadism, hyperprolactinemia and hyperthyroidism.

It is known that testosterone increases sexual interest and the frequency of sexual acts, as well as the frequency of nocturnal erections, but it's role on visual or fantasy induced erections is little to none.

f) Neurological causes:
- CNS: Parkinson's disease, encephalitis, temporal lobe epilepsy, stroke, multiple sclerosis (50-70% of patients with MS may have ED), tumors, myelodisplasia;
- periphereal nerves (trauma, diabetic polineuropahty, alcoholic neurophathy and radiopelvic surgery).

g) Penile diseases: Peyronie's disease, trauma, priapism (vascular lesions).
h) Drugs: Marijuana, Opioids, Ethanol, Antimuscarinic drugs, Antihistamine, Tricyclic antidepressants, Estrogens, Spironolactones, Ketoconazole, and many other drugs.
i) Renal failure-up to 40-50% patients on dialysis suffer from ED.

TREATMENT

Currently there are three lines of treatment for ED. The first line and the most used one is oral medication, especially phosphodiesterase 5 inhibitors. Since 1998, when the first PDE-5 inhibitor was introduced, Sildenafil (Viagra), the management of ED was revolutionized due to its high efficacy and few adverse effects. As time passed other drugs with higher efficiency and superior safety profiles became available, such as: Vardenafil (Levitra) and Tadalafil (Cialis). These drugs block the hydrolysis of cyclic GMP, increasing the accumulation of GMPc and potentiating the effect of NO [2]. For many men the treatment with PDE-5 inhibitors has allowed them to regain normal sexual function and regain self-confidence.

The second line treatment is the intracavernous injection of vasoactive drugs such as papaverine, prostaglandin E1 or phentolamine. The efficacy of this therapy is high, but the pain and the risk of ischaemic priapism limit its utilization [8]. The third line of treatment is the surgical implantation of a penile prosthesis. When the conservative therapy fails(PDE 5 inhibitors, intracavernosal injections, vacuum erection device, intraurethral suppositories with alprostadil – Is a PGE1 which increases corporeal oxygenation by promoting blood inflow) or when the patients are reluctant to any form of conservative therapy, the solution is the penile prosthesis implantation. The first penile prosthesis were introduced at the beginning of the 1970s . Since then they have been greatly improved and the surgical techniques for placement have evolved and made penile prosthesis implant a very effective treatment for ED [9]. This kind of treatment is effective and safe, and it also offers high satisfaction rates for patients and for their partners. With the technical improvement the number of complications and revision surgeries decreased, thereby the popularity and use of penile prosthesis for the treatment of ED increased.

The penile prosthesis available on the market include the one piece malleable and the two or three piece inflatable versions, each type of prosthesis having its own advantages and disadvantages. Malleable prosthesis is easier to use and have fewer mechanical problems compared with the inflatable prosthesis and they are also less expensive. The disadvantage of malleable implants is that complete penile detumescence cannot be achieved and this may be an important factor for patient unsatisfaction [10]. The inflatable prosthesis permit flaccidity and have a better functional result, but not all patients have the dexterity to use them, especially older men. Despite the implantation of penile prosthesis has been well documented, many urologists are reluctant to this form of treatment in older patients, due to the concern that older men have less dexterity and ability to operate an inflatable device [11]. The patients' satisfaction regarding the penile prosthesis implant is associated with their expectations and the performance of the implanted prosthesis [12]. Therefore, the decision regarding the type of prosthesis should be made by the doctor and by the patient, during a discussion where the doctor explains the advantages and disadvantages of every type of prosthesis, the risk of complications, the rate of satisfaction and unsatisfaction that both patient and his partner may have from this type of treatment, thus making sure that the patients will have expectations in line with reality.

The three piece inflatable penile implants are currently the most used prosthesis and their results regarding patient satisfaction are very good. The malleable and two piece penile prosthesis can be used in selected cases, where the three piece prosthesis has questionable indications (like in the case of elderly men who may have low dexterity and ability to operate such devices) [13,14].

Partners' satisfaction is questionable because few studies have investigated this problem during a long term follow-up period; although in literature the rate of partners' satisfaction is similar with men satisfaction. For more realistic results regarding this problem, evaluating the two partners separately during the follow-up period should bring out interesting results (in line with reality) [15].

Hakan Kilicarslan et. al in a recent study regarding the comparison of patient satisfaction for the malleable prosthesis (AMS 600-650) and two piece inflatable penile prosthesis (AMS Ambicor) concluded that the two piece inflatable prosthesis was found to be more successful and more likely for continous use when compared to the malleable device. A total of 72 patients had either AMS 600-650 or AMS Ambicor, but only 46 patients were reviewed during a long time follow-up. The percentages of patients with AMS 600-650 who reported to be satisfied, very satisfied and unsatisfied after the implant were 34,78% (8 patients out of the total of 23 questioned after the operation), 30.43% (7 patients out of 23) and 34,78% (8 patients out of 23). For the patients with the two piece inflatable penile prosthesis the results were: 73.91% (17 out of 23), 13.04% (3 out 23) and 13.04%. The percentages of patients who reported to be very likely, unlikely or very unlikely to continue using the malleable implants were: 30.43% (7 patients), 34.78% (8 patients) and 34.78%; in the case of the patients with the two piece inflatable devices the results were: 65.21%, 21.33% and 13.04% [16].

A study made by Natali et. al revealed that the likelihood of continuous for the two piece device AMS Ambicor was 89% (59 patients) and for the malleable device AMS 600-650 was 56% (9 patients) [13].

In another comparative study Lux et. al reported that the partners satisfaction rated 79% with the two piece prosthesis [17].

Levine related an overall satisfaction rate of 90% for men and the 82% for their partners, of a total of 131 patients, patients which benefited from the AMS two piece Ambicor implant [18].

Minervini reported that the 71% of patients using the malleable AMS 600-650 were satisfied with the implant [19].

Yoon Seob Ji in a study made on 74 patients who underwent implantation of inflatable penile prosthesis reported that the overall satisfaction was 86,8% and that 81,1% said that the prosthesis improved their sexual life. 83% of the patients in the study would undergo surgery again and 88.7% would recommend it to a friend. Only 60.4% of the patients interviewed during the follow-up period reported that they had an orgasm [20].

Mario Paranhos and collaborators established that 86.3% of patients (120 patients questioned out of 249 operated) rated their satisfaction after the implant as good, excellent or very good. The partners' satisfaction percentages was similar. The follow-up period was 40 months [21].

Humberto G. Villarreal and LeRoy Jones, in a study about penile prosthesis in the elderly men, reported that overall satisfaction was 4.3 (from a scale of 1 to 5, 5 meaning very satisfied), the ease of use was 4.1 (from a scale of 1 to 5.5 meaning very easy) and the mean use was 3,3 per month (0 to 7 times a month) [11].

Carson and associates evaluated satisfaction rate in 372 patients, group in which was used the AMS 700 CX prosthesis and it was stated that 79% used this prosthesis at least twice a month and that 88% would recommend the prosthesis for a friend [22].

There was little data regarding implantation of penile prosthesis in elderly people. As the life expectancy and longevity continuous to increase so does the ED problem refractory to first line treatment. Accordingly to Lindau, elderly couples remain sexual active even into the eight decade of life [23]. So the number of elderly men seeking penile prosthesis implantation will have a significantly increase. There are numerous potential complications of the inflatable penile prosthesis such as surgery related complications (haematoma, infections, erosion of the corpus cavernosum and even perforation) and mechanical failure (reservoir leakage, cylinder leakage, pump failure) [14,24].

The incidence of these complications depends on the follow-up period. In the immediate postoperative period, Paranhos stated that 24.5% patients reported pain, 7,9% had local infections and 8,6% had other complications such as wound dehiscence, difficulty voiding or local secretions without infection. In regards to late complications 8.6% of patients had to undergo revision surgery (12 patients out of 139 operated and followed up), of whom 4 the prosthesis had removed due to inefficacy and 8 had them exchanged. 2 of the 8 patients who had them exchanged had prosthesis fractured, 4 had inadequate size and the other 2 had extrusion of the cylinder. He remarked in his study that the risks of complication for the patients that have had radical prostatectomy previously was higher, 3,3 times higher. The rate of postoperative infections in this study was 7.9%. Paranhos explains that this high rate of infections compared to other studies is due to the experience of medical trainees, the high number of surgery in the operating rooms and the economic and social conditions of the patients [21]. The rigorous preoperatory asepsy has shown to reduce the incidence of infection to 4% from initial overall rate of 12% [25].

Jarow et. al [26] reported an infection rate of 1,8% and Gower a rate of 2.1% [27].

Merino in a meta-analysis related a lower infection rate in the case of malleable prosthesis compared to inflatable prosthesis (1.3% vs 3.5%) [28].

Menard in a study which examined over 400 patients with penile prosthesis after radical prostatectomy showed that the rate of complications for infection, revision or mechanical failure was less 5% and that the satisfaction rate was 86.1% [29]. The use of antibiotic impregnated penile prosthesis could significantly reduce the postoperative infection incidence and as well as the number of revision surgeries related to infectious complications. The overall postoperative complications are less than 5% and for infections is less than 2%. The incidence for mechanical failure is related of the follow-up period [30] and the overall incidence is around 5% [31]. Mechanical failure occurs more frequently in a case of multipiece inflatable prosthesis, due to their complexity. Malleable prosthesis due to the simple design are associated with a lower risk of mechanical problems. Lotan et al. related that the rate of survival (without technical problems) for malleable prosthesis compared to the inflatable ones is 87% vs 50% [32]. Paranhos encountered during his study a rate of mechanical problems in 3.59% of cases [21].

Atienza, in a meta-analysis regarding this problem found that the overall rate of mechanical failure was 1.4% [33]. He also found a rate of prosthesis exchange or withdrawal of 7.1%, which was similar to the rate that Paranhos described in his study of 8,68% [21].The causes of exchange or withdrawal were inadequate cylinder size, fracture of bioprosthesis (very rare, Parahos [21] reported 2 cases of patients with prosthesis fracture that didn't know of their problem and they had a normal sexual activity, this issue was found during check-ups).

Yoon Seeob Ji [20] related that 21.6% of patients (16 patients) experienced mechanical problems and 5.4% (4 patients) mechanical problems. The mean follow-up period was 98 months. The mechanical problems encountered were caused by cylinder leakage 8.1% (6 patients), reservoir leakage 1.4% (1 patient out of 16) and pump failure 1.4%. In the case of the other 8 patients with mechanical failure the cause was not found because they didn't undergo reoperation. The nonmechanical failure was due to erosion, infection of the prosthesis and other medical problems. All the patients with non mechanical failure underwent implant removal and surgical exploration. The survival rate of the inflatable prosthesis during the follow-ups over 5.10 and 15 years were 67.6%, 43.2% and 23%.

RESULTS

Compared with the conservative treatment for ED, the satisfaction rates achieved after penile prosthesis implantation are higher. According to the studies that we have analyzed, the overall patients satisfaction is 70-90%. The difference between pacient and their partners satisfaction rate is negligible, this difference ranging between 2 to 8%. The satisfaction rate regarding the adequate erection for sexual intercourse is 80-90%. The overall satisfaction rates for the malleable prostheses are lower compared with inflatable devices, 30-75%, respectively 75-90% for the inflatable prosthesis. The mechanical and overall survival rates for the malleable prosthesis range between 65-80% at 10 years, and 58-75% for the inflatable devices. Overall ease of use is rated as 78%.

Complications after implantation can be encountered in less than 5% of cases and infections in less than 2%. The likelihood of continued use is higher in the group of the patients with the inflatable prosthesis compared with the malleable ones 70-80%, respectively 50-60%. Up to 85-90% of patients with inflatable prosthesis would recommend them.

CONCLUSIONS

PPI is a high effective treatment for erectile dysfunction, refractory to pharmacological treatment. The technological improvements have decreased the rate of complications and revision surgeries which may appear after implantation, making these devices a safe solution and with great results for the men who choose penile prosthesis implantation as an answer to their problem. Many studies have related that the satisfaction rate after the operation was high, both for the patients and their partners [20]. The patients unsatisfaction after the implantation, was related to the unnatural feel of the sexual relations, due to the delayed ejaculation which was encountered in few cases and also because of the partners dissatisfaction, situation that may be related to the fact that the expectations were higher than the results. Thus before the operation, the doctor should make sure that the patient and his partners will have expectations in line with reality. Today, the three piece inflatable prosthesis is the most preferred one. Regarding the long term survival and complications of the penile prosthesis, the malleable prosthesis have a lower rate of mechanical problems than the inflatable ones, due to their less complex technological design, but patients satisfaction is higher in the group of inflatable prosthesis because they permit flaccidity and they have a better functional result. Patients who undergo implantation for the first time have a lower risk of postoperative complications compared with the patients who have had several interventions for different complications related to the penile prosthesis implant. The likelihood of continued use is higher in the group of the patients with the inflatable prosthesis compared with the malleable ones. The success of the implantation is very important, because the surgical revision is associated with a worse prognosis and a higher rate of complications. Regarding diabetes, several studies have shown a small correlation between diabetes mellitus and postoperatory infections [34,35]. Diabetes mellitus and radical prostatectomy are associated with a higher of postoperative complications. PPI enhances sexual capacity and self-confidence, therefore it should be considered as a final choice for patients with ED refractory to drugs.

TOT versus TVT – mesh surgical treatment in stress urinary incontinence

Ovidiu Bratu[1,2], D. Marcu[1], D. Spînu[1], A. Rădulescu[1], I. Oprea[1], Dan Mischianu[1,2]

Abstract: *Introduction: Stress urinary incontinence is a highly debilitating condition, with an important impact over the quality of life. When the conservative treatment fails, the surgical treatment is a viable solution. Minimally invasive sling procedures have become the gold standard of surgical management for stress urinary incontinence (SUI) in women.*

Material and methods: The study was conducted on 68 patients with stress urinary incontinence, 52 have undergone the retropubic tension-free vaginal tape and 16 patients were operated using the transobturator tape procedure. All the patients were evaluated before the operation and the indication of the surgical treatment was established on the basis of physical examination (all the patients had positive cough test), abdominal ultrasound (to determine postvoid residual urine volume), urinalysis and urine culture (the majority of the patients have had before the operation recurrent urinary tract infections).

Results: The satisfaction was similar in both groups of patients, with an average satisfaction rate of 91% for TVT and 86% for the patients who have undergone TOT procedure. The patients were in a proportion of 78,9% at menopause, with an average number of natural births of 1.9 and a mean BMI of 28.2. Regarding the surgical duration, this has varied between 20 and 40 minutes, being higher in the TVT cases (up to 5-7 minutes longer than TOT), because cystoscopy was performed during the operation to verify if the bladder was perforated or not. The urethral catheter was removed immediately after the operation in the case of the TOT procedure and in the day after the operation for the patients who have undergone TVT procedures (all of these patients associated genital prolapse). The hospitalization time was 3 days. We haven't encountered significant intraoperative and postoperative complications.

Conclusions: The TOT and TVT procedures have proven to be highly effective and safe methods in the treatment of SUI. There are no significant differences regarding the efficacy of these two surgical methods, but the risk of intraoperative complications is a little higher for the TVT procedure. The mid urethral sling procedures improve significantly the quality of life for patients with stress urinary incontinence.

INTRODUCTION

Female stress urinary incontinence is a major public health problem, with psychological and social effects and with an important impact over the quality of life. Stress urinary incontinence is defined as involuntary leakage of urine through the urethra during physical activities which increase the intra-abdominal

pressure, like laughter, coughing and sneezing, climbing stairs. There are numerous factors which contribute to the appearance of SUI: muscle weakness of pelvic diaphragm secondary to vaginal births, gynecological interventions, overweight and obesity, hormonal disorders. When the conservative treatment (bladder control exercises and pelvic floor muscle training, lifestyle modifications such as dietary habits, weight loss and physical activities) fails, the surgical treatment is a viable solution for SUI.

The first surgical treatment for stress urinary incontinence was described by Burch in the early 1960s and for almost 30 years, till the mid 1990s, it has remained the standard treatment for stress urinary incontinence. The long term follow-ups have suggested that this type of surgical treatment is effective, with a satisfaction rate at 5 years after the operation of nearly 80% and at 10 years of 70%. At the beginning of the 1990s, DeLancey established that the physiopathology of the SUI is associated with a defect at level of the bladder neck and urethra, related with the laxity of the surrounding tissue and as well as with the insufficiency of the urethral sphincter. He reported that the urethra lays on a layer of the endopelvic fascia and anterior vaginal wall and it is stabilized to the lateral by attachements of the levator ani muscle and arcus tendinous fascia. The urethral closure is conditioned by the urethral compression against the support offered by the anterior vaginal wall and the pubocervical fascia. This was the beginning of a new era in the treatment of SUI, the minimal surgical invasive treatment which would prove to be very effective.

In 1995, Ulmsten and Petros described the minimal invasive technique of retropubic tension-free vaginal tape. It was the first generation of sling operations, which used a polypropylene mesh. This procedure involves the blind penetration of the paraurethral and the retropubic space with a needle and the operator must exit with the needle behind the pubic symphysis. Because of its good results and low complication rate, it has become the solution for SUI. It is cited in the specialty literature that the rate of success ranges from 80 to 95%, after more than 5 years after the operation. Although the effective rate was high, it exist the intraoperative risk of complications such as bladder and bowel perforation and vascular injuries. As a solution to these concerns, Delorme described in 2001 another minimal invasive technique, the transobturator tape procedure. As well as the TVT the TOT is also a blind procedure. During the TOT surgery the puncture is performed at the clitoral level of the inferior ramus of the pubic bone and the operator must pass with the needle through the obturator foramen. This is the second generation of sling operations for SUI. It has been proven that the efficacy of the TOT procedure is similar to the TVT and with this type of procedure the risks of perforating the bladder or the bowels have disappeared, but more patients have groin pain postoperatively and vaginal or urethral erosion due to the polypropyline mesh. Both procedures are in current use for the SUI treatment, but because of its lower complication risks and similar efficacy, the TOT procedure is more popular.

MATERIALS AND METHODS

The purpose of this paper is to present our experience at the Urology Clinic of the Central Military Emergency University Hospital “Dr. Carol Davila” regarding the minimally invasive surgical treatment of stress urinary incontinence, using the vaginal sling procedures of TVT and TOT. We have analyzed several variables like: patient age, the number of vaginal births, body mass index, and gynecological interventions like hysterectomy. We present our cases and experience regarding perioperative complications and their management and as well as the efficacy rates, compared with other studies.

Between March 2010 and November 2015, in the Urology Clinic of the Central Military Emergency University Hospital “Dr. Carol Davila”, a number of 68 patients with stress urinary incontinence have been operated, using the minimally invasive technique of retropubic tension-free vaginal tape or the transobturator tape procedure. Out of the 68 patients who were admitted in our clinic for the surgical treatment of SUI, a number of 52 patients have undergone the transobturator tape procedure and only 16 patients were operated using the tension free vaginal tape technique. The TVT procedure was used only in the cases of the patients who associated genital prolapse. TVT has the same assembly principle as the TOT, but the incisions are made in the suprapubic region. The intraoperative complication risks, like bladder or bowel perforation, are higher in the case of the TVT compared with TOT. Therefore cystoscopy is essential after puncture. In all the cases with TVT we have performed cystoscopy to exclude a potential bladder perforation. Before the operation, all the patients were examined and the indication of the surgical treatment was established on the basis of physical examination (all the patients had positive cough test), abdominal ultrasound (to determine postvoid residual urine volume), urodynamic studies (testing was not performed in all the cases), urinalysis and urine culture (the majority of the patients have had before the operation recurrent urinary tract infections).

RESULTS

The mean age of the patients was 60.9 years. The patients were in a proportion of 78.9% at menopause and the average number of natural births was 1.9 ranging between zero and five. Mean BMI was 28.2, ranging from 23.3 to 37.4. Regarding the surgical duration this has varied between 20 and 40 minutes, being higher in TVT cases (up to 5-7 minutes longer than TOT), because cystoscopy was performed during the operation to verify if the bladder was perforated or not. The mean operative time was 27 minutes. Both surgeries required a 3 day hospitalization, the patients being discharged in all the cases the day following the surgery. The urethral catheter was removed immediately after the operation in the case of the TOT procedure and in the day following the operation for the patients who have undergone TVT procedures (all of these patients associated genital prolapse). In what concerns the urinary residual volume in the first days after the operation, we haven't noticed significant differences between the two types of procedures (the patients didn't accuse incomplete bladder voiding). All the patients were reevaluated at one month after the operation using the cough test, abdominal ultrasonography to determine the postvoid residual urine volume and to find potential complications secondary to the procedure. The long-term treatment outcomes were evaluated after 3, 6 and 12 months. Regarding the patients satisfaction, it was considered after the evaluation that the SUI was cured if the patient was completely continent, improved if partial urinary incontinence remained after the surgery and failed if the urinary incontinence remained the same or got worse after the surgery. The patient satisfaction was similar in both groups of patients, with an average satisfaction rate of 91% for TVT and 86% for patients who had undergone TOT procedure. Our results are in line with data from specialty literature.

J. Y. Han et all in a study about the effectiveness of TVT and TOT procedures in women with overactive bladder and stress urinary incontinence, stated that TVT and TOT procedures have decreased the proportion of the daily incontinence in these patients, with a slightly higher efficacy in the TVT group. In a study published in 2013 the ”Scandinavian Journal of Urology”, V. Nyyssonen concluded that 70% of the patients that were included in the study, with symptoms of detrusor over activity, declared significant improvement after the mid urethral tape surgery. There was no significant difference between the two operating techniques.

Cerniauskiene and collaborators in a comparative study regarding TOT and TVT outcomes reported that the satisfaction rate for the patients who have undergone the TOT procedure was 81,3%, meanwhile the satisfaction rate for the TVT group was 90%.

Zyckowsci et al stated in their comparative study regarding the TVT and TOT surgery, that the patient satisfaction rate at 6 months after surgery was 96,4% for TVT patients and 96.1% for TOT patients. Regarding the cough test and pad test, they have stated that it was negative in 91.5% and 94.4% in TVT cases, and in 93% and 93% TOT cases. The findings in our study were similar to general literature. We have observed in our study that the cough test was negative for 91.2% of TVT cases and 92% of TOT cases at 6 months, and the pad test was negative for 94% of TVT cases and 92.8% of TOT cases at 6 months postoperative. We haven't encountered significant intraoperative and postoperative complications. We haven't had significant bleeding during the interventions. The mean blood loss was under 25 ml. Local hematoma was encountered in 5 TOT cases and in only one TVT case and conservative treatment was effective. We haven't had any bladder or bowel perforation complications. We have encountered one case of relapse of incontinence due to the exaggerated physical activities, at two and a half years after the operation. In this case, we have performed a second intervention. We have removed the mid urethral portion of the tape and we have performed the tension-free vaginal tape procedure. The results at 3 and 6 months after the operation were good, although it is mentioned in general literature that in the case of reintervention for relapse of SUI the outcomes may not be as good as in the case of the first operation.

De novo overactive bladder symptoms ranged between 3 and 4.5% without differences between TOT and TVT patients. The pharmacological treatment which was applied in these cases has had good results. There are studies in which it is mentioned that the incidence of the overactive bladder symptoms ranges between 4 and 30 % after the operation.

Bladder botulinum toxin A injection and percutaneous sacral nerve modulation have proven to be good alternatives for the TOT and TVT surgery. Since its introduction (2005-2006) the number of patients who were admitted for bladder botulinum toxin A injections has increased constantly, overtaking in 2010 the number of TVT/TOT procedures. So far we haven't applied this method of treatment for the SUI.

With the passing of the time, the number of patients who have undergone TOT/TVT surgery and have chosen to remove their tapes grows. Most tape removals are performed at a relatively short time after the procedure, the main cause being urinary retention or tape extrusion. We haven't encountered such situations in our study.

CONCLUSIONS

The minimally invasive surgical treatment of SUI (TOT/TVT) has become the gold standard for patients with this debilitating condition. Mid-urethral sling surgery is performed to fix the urethra and involves few anatomic changings in the surrounding tissues.

These procedures have proven to be highly effective, increasing the quality of life for the patients who suffer from SUI. Regarding the efficacy rate of this two type of procedures it hasn't been noticed significant differences in the study that we have done, our results being in line with specialty data.

In terms of complications the risks are higher for the TVT procedure, due to the risk of bowel or bladder perforation. To exclude this possible accident, which may happen during TVT, cystoscopy is essential. Therefore, the TOT procedure has become more popular.

Till the introduction of TVT and TOT, SUI was either simply accepted or required invasive surgery.

Penile fracture – clinical case presentation

C. Farcaș[1], V. Botea[1], R. Popescu[1], Marius Dinu[1], Ovidiu Bratu[1,2], D. Spînu[1], Dan Mischianu[1,2]

INTRODUCTION

Fracture of the penis is a rupture of the tunica albuginea of the corpus cavernosum, usually while the penis is rigid and erect. When erect, the albuginea layer stretches so far until its thickness reaches approximately 0.25 – 0.5 mm, compared with a 2 mm thick when flaccid. Thus the erect penis is much more vulnerable to serious damage from blunt trauma than the pendulous, flaccid penis. The most common cause of penile fracture is vigorous vaginal intercourse, more likely when woman is on top, but it can also occur during masturbation, forced bending of the erect penis or any mechanical trauma to the erect penis. The classic presentation described by the patient cracking or popping sound, followed by rapid detumescence, severe pain, ecchymosis of the penile skin, and swelling of the affected side with deviation of the penis shaft away from the affected side. In most cases, the penile fracture is a transverse corporeal tear close to the corpus spongiosum on the ventral aspect of penis shaft or on the lateral aspect and the tunical tear is usually 1 to 2 cm in length. The rupture can involve one or both corpora cavernosa as well as corpus spongiosum with the contained urethra therefore urethral rupture can also occur in. Most urethral injuries are associated with gross hematuria, blood at the meatus or inability to void, although the absence of these findings does not definitively rule aut urethral injury.

DIAGNOSIS AND IMAGING

The penile fracture is considered by the most to be a clinical diagnosis, with little need for imaging if the patient presents with a convincing history and physical examination. However given that urethral injury occurs not infrequently, preoperative exploration of the urethra should be considered when urethral injury is suspected (urethrography or flexible/rigid cystoscopy). There are numerous reports of the accuracy of cavernosography and magnetic resonance imaging (MRI), inspite of their accurate results, they are sometimes too invasive, time consuming or costly to justify, particularly when the diagnosis can be established by clinical examination. Ultrasonography although noninvasive and easy to perform is also associated with significant false-negative studies. Another condition that may mimic penile fracture is rupture of the dorsal penile artery or vein during sexual intercourse, in these circumstances physical examination may not be adequate for definitive diagnosis of a corporeal tear and further investigations should be performed like MRI, ultrasonography or even surgical exploration.

MANAGEMENT OF PENILE FRACTURE

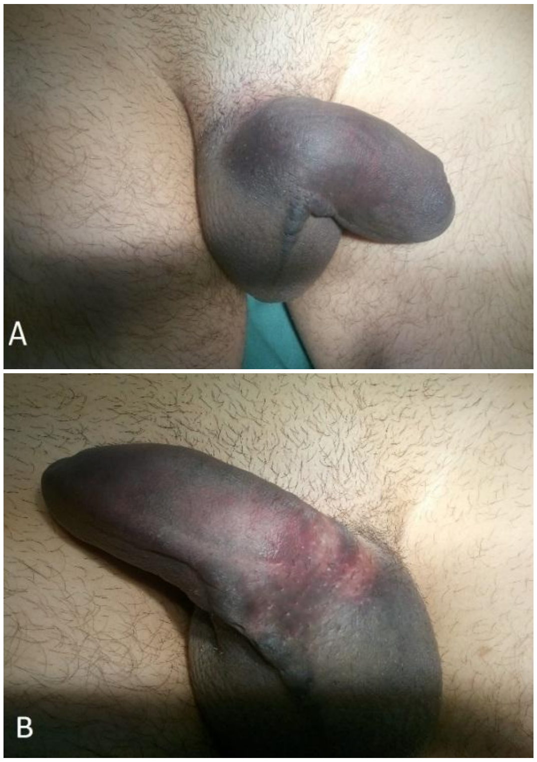
Multiple publications indicate that suspected penile fractures should be promptly investigated and surgically repaired. Many reports show low complication rate and good outcomes as a result of immediate surgical repair, (less than 5% penile curvature after immediate surgical repair – El Atat et al, 2008) as the favorite approach for treatment of this urological emergency. Conservative management can also be an option in patients with uncomplicated albugineal tears, without extensive hematoma or urethral injury, but most untreated fractures usually develop delayed and persistent penile pain or curvature with erection. Conservative management of penile fracture has been associated with penile curvature in more than 10% of patients, abscess or debilitating plaques in 25% to 30%, and significantly longer hospitalization times and recovery (Meares,1971; Nicolaisen et al, 1983; Kalash and Young, 1984; Orvis and McAninch, 1989).

Although small lateral incisions may be used for localized hematomas or palpable tunical defects, a distal circumcising incision is the best option in most cases thus providing exposure to all three penile compartments. For the closing of the tunical defect is recommended to use interrupted absorbable suture 2-0 or 3-0. Deep corporeal vascular ligation or extensive debridement of the underlying erectile delicate tissue should be avoided. Timing of the intervention may also influence the long-term outcome of erectile function or postoperative complications in the way that the patient undergoing surgical repair intervention in the first 8 h after injury has significantly better long-term results than those having surgery delayed 24-36 h after fracture occurrence (Asgari et al, 1996; Karadeniz et al, 1996).

PATIENT, METHOD AND RESULTS

A 31 years old patient presents in the emergency department in our hospital at approximately 03:15 a.m., this being the third medical unit he was attending that day, accusing pain in the external genital area associated with extended hematoma of the penis and scrotum with the deviation of the penis on the left side (Figure 1A). Further anamnesis discovers posttraumatic injury of the penis while sexual intercourse that happened at approximately 01:00 a.m. The patient describes powerful bending of the penile shaft, and at the same time strong local pain, accompanied by a snapping sound and after that immediate detumescence of the penis with decrease in pain intensity. Patient describes urine voiding normal and no bleeding out of the urethra.

Figure 1. Extended hematoma of the penis and scrotum and pathological deviation of the penis shaft on the left side (A)



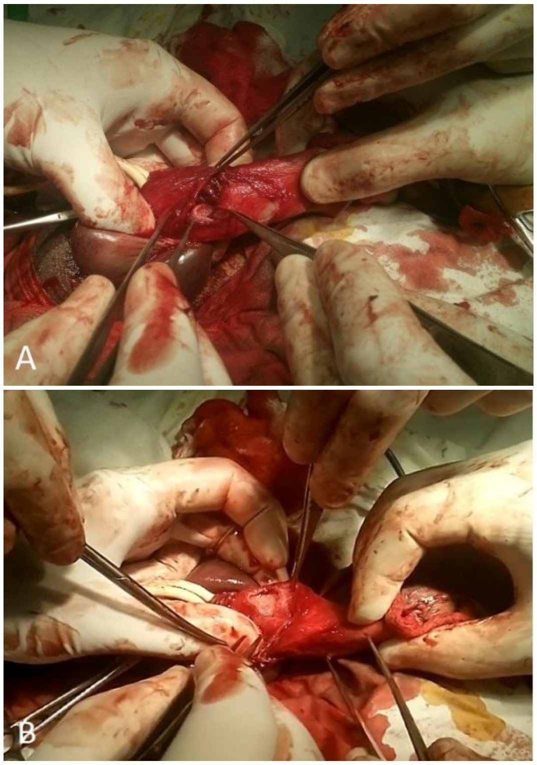
The patient is admitted in our department and undergoes a soft tissue ultrasound that reveals a local hematoma of the penis and a small breach of approximately 3-4 mm in diameter which is situated on the ventral aspect of the right cavernous body, of the proximal third of penis shaft.

Emergency surgery is decided, with spinal anesthesia at 08:00 in the morning (7 hours after the injury occurrence).

After local antiseptic measures, a 14 Fr. Foley catheter was placed before the beginning of the intervention. A distal circumcising incision is made at approximately one cm proximal of the coronal sulcus, followed by degloving the penis, and exposing the tunical fracture site in the albuginea.

The tunical tear was fond on the ventral aspect of the corpora cavernosum at a distance of 3-4 cm from the base of the penis.

Figure 2. A: albugineal tear on the left cavernous body. B: albugineal tear on the right cavernous body.



The rupture site was much greater than the one observed on the ultrasound scan. The real size of the tear was about 3 cm and involved both cavernous body on their anterior aspect, as well as the septum of the albuginea underneath the spongy body (Figure 2, A and B).

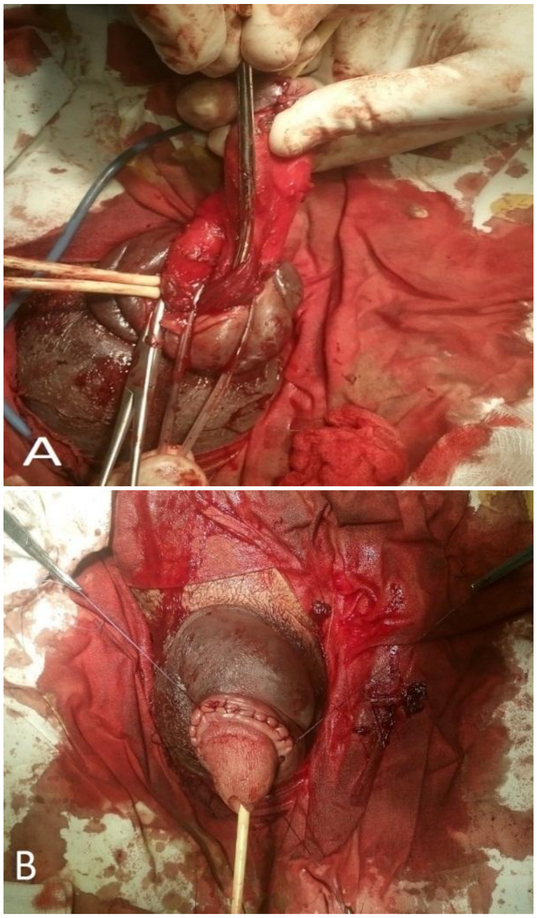
The spongy body was carefully dissected from the corpora cavernosa and so the entire length of the transversal rupture was individualized.

A temporary elastic Tourniquet at the base of the penis was necessary for local control of bleeding.

Defect repair was performed with separate absorbable 3-0 USP sutures. For the full length of the breach 14 to 15 separate sutures were needed. Final aspect of the repaired defect of the tunica albuginea can be seen in both pictures below (Figure 3, A-B).

The patient's evolution was favorable under antibiotic therapy for 5 days with no infectious complications. Second day postop he mentioned a mild morning erection although he was under treatment with Cyproterone acetate 50 mg twice a day and Diazepamum 10 mg a day in two doses.

Figure 3. A: ventral aspect of penis with the spongy body mounted on a lasso and the albugineal surure. B: final aspect after suture of the skin.



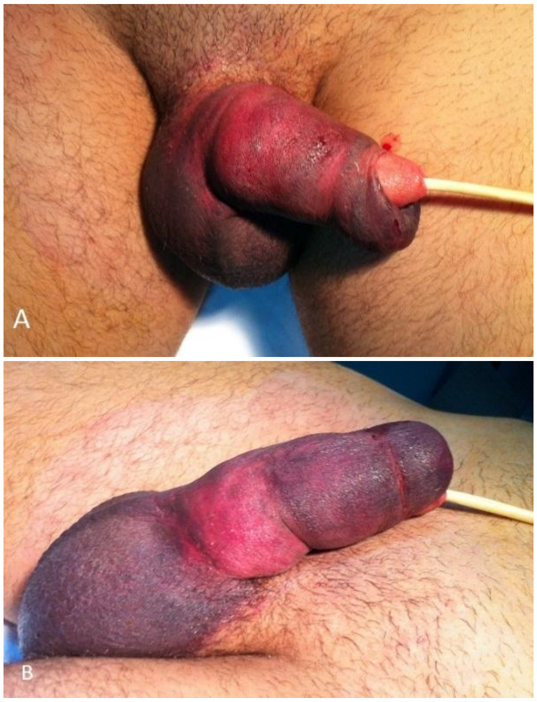
DISCUSSION AND CONCLUSION

Penile fracture is a rare case of urological emergency that should undergo in most of cases emergency surgical treatment.

The immediate surgical repair attitude (<8 h) is the preferred approach for treatment of penile fracture as reported in numerous centers around the world due to their low complication rates.

While the conservative approach is described in patients with small and uncomplicated tears, most unrepaired fractures develop late penile curvature or pain with erection.

Figure 4. Aspect of the penis and scrotum the second day postoperatively while patient still carries a Foley catheter.



The urgency of surgical exploration justified in our case the discrepancy between imaging findings and the reality found during the surgical exploration.

Albugineal tear that involves the both corpora cavernosum is extremely rare and also usually is associated with urethral injury, which in this patient, the last one, was not the case.

The incidence of concomitant urethral injury is approximately 20 % in Europe and the USA. Most urethral injuries are associated with urethral bleeding or gross hematuria or even inability to void, but also, the absence of these signs does not exclude a potential urethral injury.

About the beauty of urology…

Dan Mischianu

Gral (R) Prof DAN MISCHIANU

Chief of 3rd Clinical Department,
Faculty of General Medicine,
Carol Davila University of
Medicine and Pharmacy,
Bucharest, Romania

Urologic Surgery is one of the most beautiful, exciting, spectacular and unpredictable surgical specialties.

From 1907 it stands as a specialty of it's own, breaking free from general surgery, as other surgical specialties, Professor Felix Guyon being the godfather of this specialty. In the last 20 years, urology itself has become a "tree" of sub-specialties, from which medical branches such as andrology, urogynecology, oncological urology have developed. These medical strains tend to become independent.

From 1909 urology begins to be recognized in Romania, as a specialty of it's own, time when Professor Petre Herescu, Guyon's student, establishes this speciality within Coltea Hospital. Over time it has experienced a steady development as few specialties have had. Over the last century, romanian urology has given world renowned characters, which have settled romanian urology in a place of honor.

We have the strength to affirm that urology is "a friendly specialty", not only with the surgical specialties, but also with other medical specialties. There are many surgical and non-surgical specialties, whom we as urologists can offer our help, or an advise, or a surgical procedure. Urology can have harmonious collaborations with many other specialties, and I give as example, the selective arterial embolization after PNL or arterial stenting in erectile dysfunction, procedures which are performed by interventional radiologist.

Like in any other surgical specialty, the urologist has two important "friends", with whom the collaboration must be at the highest level. I refer of course to the anesthesiologist and to the pathologist.

Urologic surgery faces or may face urgent situations, emergencies which if not noticed in time and skillfully managed it could have a poorly outcome for the patient. Among these situations, we give as an example just a few: obstructive anuric acute renal failure, urosepsis, urological trauma with hemodynamic instability etc.

We haven't taken into account the postoperative hematuria, on one hand due to urological diseases, but also secondary to various other conditions, such as an eventual hepatic cirrhosis or secondary to an overdose or misuse of anticoagulants, out of which we are almost convinced that it is a practice at "national" level at the indications of the anesthesiologists.

These pathologies mentioned above are just a few aspects of what it represents the "salt and pepper", but also the challenges of an urologist's life.

While the general surgeon performs, with difficulty, for example a retrocecal appendectomy and waits with some concern for the 5th day peritonitis, the urologist may be in the situation, in which he must promptly intervene at 2-3 hours after the patients admission or after a correctly performed intervention, to stop a bleeding which may occur without any explanation or for an obstructed drainage.

I have discovered slowly and quite late the charm of urology. Later I have learned that it is a surgical specialty much better encoded than abdominal surgery. Urology has an ethiopathogenic and topographic diagnosis more accurate and much more faster. I have later discovered it's minimally invasive valences regarding diagnosis and treatment, for example the ability to perform endoscopic surgery, laparoscopic and robotic procedures, with the possibility of "one day surgery" hospitalization and with maximum results for the patient. In this context it should be noted that robotic surgery, very popular nowadays, was initially born in the specialty of urology, for one purely urologic intervention, the radical prostatectomy.

Certainly the technological developments have greatly influenced the evolution of urology. There have been no new surgical devices that couldn't be used in urology. Nowadays the classical interventions, have come to have a smaller proportion compared with those listed above. For instance, regarding urinary lithiasis, only 1% of cases are treated using open surgery.

I do not know how urology will look over a few decades. Perhaps in the future and one not so distant, the young residents that I try to teach and mold, will operate Earthlings on another planets, using consoles such as the "Da Vinci " from now...

Finally, without having a morbid curiosity, I am satisfied with what I have seen, realized and undertook during my active urological lifetime!

Minimally invasive surgical techniques – robotic surgery

Florin Săvulescu, Costin Duţu, Cristian Cârlan

Da Vinci robotic surgical platform is the result of many years of research of the military physicians from United States Army. This platform was initially intended to operate in close proximity to the battlefield, it was supposed to allow for complex surgeries without threatening medical personnel, but also to ensure a high survival rate among the wounded. Basically, after a soldier was wounded, he was supposed to be taken away from the front line, transported to the first sanitary structure which had this platform available and a surgical team from long distance, satellite connected, performed the surgery. The advantages of this course of action are related to the fact that the team is permanently safe and the injured person benefits from the experience of a well-trained surgical team.

Due to the large amount of information transmitted between platform components, which means millions of operations performed each second, and the impossibility to secure a channel for information dissemination, even more difficult in a hostile environment such as in the vicinity of the front line, and the long preparation of a patient to be subjected to a robotic surgery, the platform is not in current use of military doctors, the way it was originally intended. So far, only one surgery was performed in which the operator was far away from the patient. The two surgical platform elements were arranged one in the United States and one in France. During the surgery, the transfer of information was made by satellite, with great efforts to secure the information channel, as well as with the suspension of any satellite phone links between the two countries.

The advantages desired by military doctors have proved to be far from being put into practice, however, their research work led to the development of the best technology that allows for minimally invasive surgery. In 2015, worldwide, about 3,400 platforms daVinci were installed: 2295 in the United States of America, 573 in Europe and 7 in Romania.

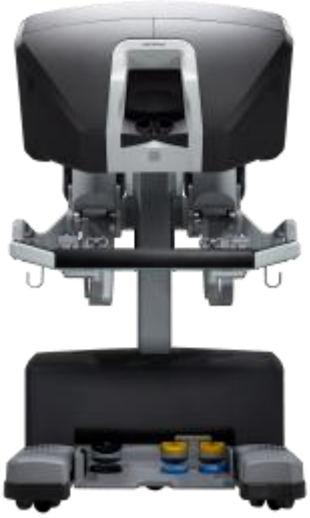
Robotic surgical platform consists of several components which will be described below. Using the system is only possible if all three components are available, none of them is optional. Although there are three components, they are interconnected and have the same purpose: to allow for a minimally invasive surgery in maximum security conditions for the patient. The system combines technological advantages: high resolution three-dimensional image, video image stability and filtering of surgeons' hands unwanted movements, with the surgeons' experience and ability to make decisions in real time.

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

Operator surgeon’s console consists of three parts. The video system allows viewing intracorporeal images in a tridimensional manner thanks to the two images submitted separately for each eye; here, there is also a number of sensors that detect the presence of the surgeon at the console, this thing is necessary as a safety measure to block chaotic motion of the device arms inside the body if the operator is absent. The second component of the console is represented by the console commands for each hand, called "master controls" and a series of commands for adjusting an ergonomic position. This component records the surgeon's hand movements allowing this information to go to the working forceps. The pedals system is the last component of the console, here it is possible to activate several functions for the working tools: electric coagulation or sectioning, handling video camera, change the working arm: the surgical system has three arms and it is necessary to change one tool with another for a certain hand. The whole assembly allows adjustment on more axes of all the components, depending on the preferences of the operator, the scope is to obtain an ergonomic position. If more surgeons use the equipment, the system stores each surgeon’s preference, and when the personal account is activated, it recreates the ergonomic position preferred by each surgeon.

Figure 1. The working console on which one can notice the three subcomponents from top to bottom: video playback system, master control, crank



Patient's charter is like a tower which has three working arms attached and a video camera arm. This charter, as its name implies, is beside the operating table. On each working arm, a certain tool is fixed and it is activated by a pulley system that allows movements in the seven degrees of freedom. Patient's charter only performs commands coming from the surgeon’s console, it has no autonomy to make decisions, it can not be programmed to execute movements without commands in real time. Fixing / replacing instruments is performed by a surgeon who is next to the patient, he is also the one who places all working cannula into the patient’s body. The working tools have a diameter of 8 mm and reproduce, in miniature, the instruments used in open surgery.

Figure 2. Patient's charter with the three working arms for tools and the video camera arm.

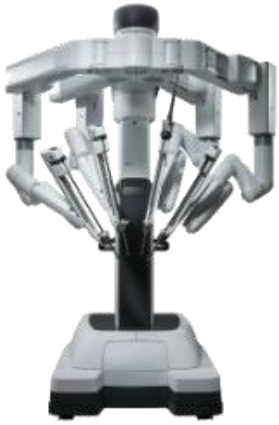


Figure 3. Working tools

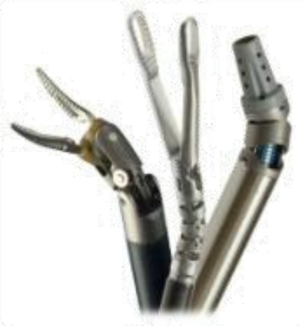
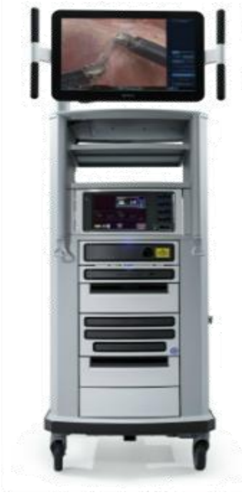


The video system displays intracorporeal images on bidimensional monitors in the operating room. This system allows recording of images and setting of certain parameters. Here lies the source of light transmitted to the intracorporeal video camera through an optical fiber. All components described above are dependent on the presence of at least two surgeons, the system is not designed to fulfill the role of the surgeon but to support surgery by involving the present technological advantages.

Figure 4. Video tower and bidimensional monitor of high resolution



The three systems are interconnected by optical fiber since the information flow is very high.

Robotics is a minimally invasive technique, similar to laparoscopic surgery, in which working tools are inserted through small incisions of 5-15 mm in the peritoneal cavity through which cannula are introduced to work. Comparative studies between open surgery and robotic surgery have highlighted the following advantages in favor of robotic surgery: shorter stay in hospital, reduced bleeding, less postoperative pain, faster social reinsertion, small incisions that allow a much quicker recovery and lower risk of developing eventrations. Patients who have no indication for minimally invasive surgery, do not have indication for robotic surgery either.

The recommendations of robotic surgery are the surgeries that require access to limited spaces, inaccessible for open surgery and restricted by the small maneuverability of laparoscopy instruments. In urology, robotic prostatectomy is considered as the "gold standard". As a general idea, robotic surgery approach is indicated for the organs situated at the top and bottom pole of the peritoneal cavity, where limited space and difficult access are not impediments for daVinci surgical system instruments.

Complications can occur in robotic surgery just as it happens with any surgery, the maximum risk is death. Complications that may arise during surgery are: intraperitoneal organs injury, intraoperative bleeding, septic complications. Another factor to be taken into consideration is the human error, system failures or potential complications of anesthesia.

At this time, da Vinci surgical platform is the most advanced tool that allows a minimally invasive surgery. A very important element about the functioning of this system is that it can not "operate" independently; it cannot be programmed to carry out independent actions. It must be seen only as an extension of the arms of the surgical team members, executing commands coming from the surgeon at the working console, under the supervision of at least one surgeon.

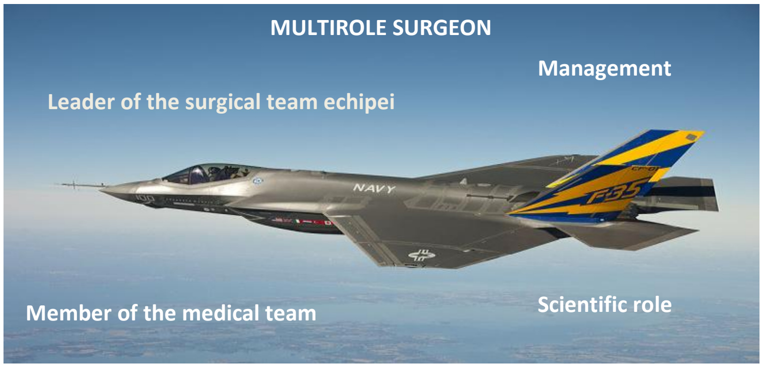
SYSTEMATIC REVIEW

Surgical team and surgical communication

Costin Duţu[1], A. Luchian[1], Elena Stârcu[1], Florin Săvulescu[1]

A significant percentage (43%) of medical errors is caused by errors in communication between healthcare professionals or between them and the patient. Today the surgeon has a multiple role (leader of the surgical team, member of the medical team, scientific role, management role)(1).

The surgical team has the duty to ensure and promote a positive work environment that improves team performance and maximizes outcomes for patient's safety (2).



MULTIROLE SURGEON
Management
Leader of the surgical team echipei
Member of the medical team
Scientific role

The most important attributes, that are critical to the development of high performance teams, are membership and leadership.

Membership presupposes the following (6):
- To understand the role and responsibilities of the teammates
- To encourage input from all members (young people!)
- To respect the role and competence of other specialties colleagues
- To respect team leaders
- To share the objective of high quality in patient treatment
- To trust the right to speak and to intervene
- Commitment to teamwork for the patient's interest

Leadership comes with a clearly defined role, especially in critical situations, which implies a style that minimizes the difference in status and power, suitable under particular conditions, designed to seek permanent information from team members and make decisions based on these (6).

Effective communication in the surgical team should be:
- Complete
- Clear – fully understood information
- Short – concise and organized information
- Relevant (timely)

In order of most important characteristics, surgical team members should feel engaged and involved in a common goal, together with mutual trust and respect (2).

In a safe interpersonal environment, team members

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

should not hesitate to express their views, to challenge each other positively, to raise certain issues without fear of ridiculous or subtle attacks. They must also feel safe to discuss errors and mistakes (5).

Table 1. Behavior strategies which influence the performance of the surgical team (7)

Positive attitudes	Negative attitudes
Listening to and exploring others' opinions	Aggressive challenges
Clarification of ideas; Requests for alternative explanations, thoughts or opinions	Distrust of alternative ideas
Supporting and encouraging members of the surgical team	Sarcastic behavior
Challenge of colleagues in a respectful manner regardless of their status	Ignore, dismiss, mock at other points of view
Disputes resolution in a constructive way by explaining the decisions that were made in a fair manner	Assuming to know the absolute truth due to position or knowledge
Appreciation, recognition of merits, contributions from others	Lack of appreciation and regular criticism without recognition of positive contributions
Search and accept feedback (positive or negative) regarding one's contribution and performance	Feedback ignorance and disregard
Own assessment and evaluation of the performance and contribution within the team	

Team STEPPS - team actions (4).

1. BRIEF: short session before surgery, discussing the team members, the role of each team member, expectations setting, discussing potential problems, anticipate unexpected things

2. HUDDLE: ad hoc session to restore certain conditions, situations, plans

3. DEBRIEF: Discussion performed after surgery, meant to improve team performance - aiming at understanding the role and responsibilities of each team member; surgical equipment problems; other improvements to the surgical procedure; lessons to be learned further.

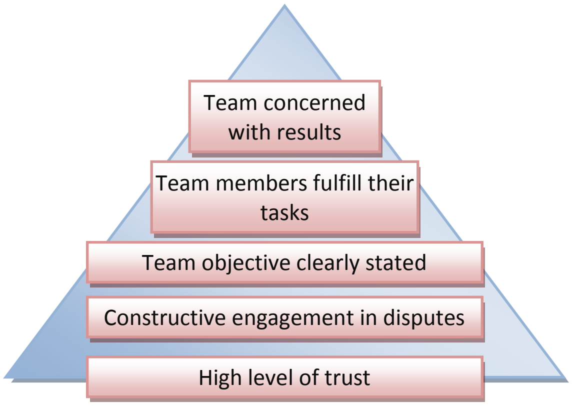
Within a team, an important thing is the coordination of tasks leading to a better awareness of each individual performance and also of the team performance, meant to encourage the members' desire to offer support to the others, thereby increasing the ability of the team to remain flexible and adaptable to changing circumstances (3).

A simple way to review and reflect on performance is to answer the following questions:
- What did I do well?
- What could be done better?
- What should we not do anymore?
- What should we continue to do?

Table 2. Errors observed in operating rooms classified by behavior categories (8)

Behavior category	Errors
Communications/decisions	The surgeon does not provide enough information to the anesthetist
Preparation/planning/ vigilance	The inability to predict certain events during a complex procedure; Failure to monitor other activities of the team
Information dissemination	Failure to inform own team
Inquiries/statements	Failure to comply with the conclusion of a discussion on an alternative procedure
Interpersonal relations/ group climate	Hostility and frustration due to poor team coordination
Auto criticism	Inability to learn from certain situations
Disputes management	Disputes between doctors from the surgery team and anesthetists not solved.

Figure 1. The structure of a performing team (9)



Team concerned with results
Team members fulfill their tasks
Team objective clearly stated
Constructive engagement in disputes
High level of trust

CONCLUSION

Communication skills are a key component in surgical practice, which can be taught, learned, improved and this will maximize performance and enjoyment in clinical practice.

Interprofessional communication problems are the leading cause of many medical errors.

Structured communication protocols such as SBAR are designed for effective and complete communication (4).

SYSTEMATIC REVIEW

Article received on November 1, 2015 and accepted for publishing on November 19 2015.

Clostridium difficile – an emerging plague

D. Spînu[1], Ovidiu Bratu[1,2], R. Popescu[1], D. Marcu[1], A. Rădulescu[1], Dan Mischianu[1,2]

Abstract: Introduction: Clostridium difficile infection stands nowadays as one of the major emerging health problems still underestimated. Only in 2009 the European Society of Clinical Microbiology and Infection (ESCMID) was able to publish guidelines for this serious disease. Actually the guidelines were updated in 2013 so we can speak of a united action towards the resolution of this healthcare problem.

Methods: This is a review article aiming to shed light in various aspects of clostridium difficile infection as clinical presentation, symptoms and signs, therapeutic options and risk factors with a focus on urologic pathology.

Conclusions: This type of infection represents a challenge from many points of view like treatment, relapse approach, mortality, morbidity, germ' s adaptability to treatment and last but not the least the outbreak of different aggressive strains like B1,NAP1 or ribotype 027 toxinotype III.

Keywords: Clostridium difficile infection, treatment, diarrhea

INTRODUCTION

C difficile was first described in 1935 by Hall and O'Toole as a Gram positive anaerobic commensal rod[1]. It took 43 years to discover the C difficile toxin in patients with pseudomembranous colitis.

The classic strains release two toxins A and B both of them monoglycosyltransferases causing colonic tissue damage. The name Difficile was given because of the the difficulty they had culturing this anaerobic bacterium on conventional media.

The interesting part is that from a nosocomial infection nowadays it appears to have spread to communities and what is more problematic to antepartum period, pregnant women and children[2].

The problem with this pathogen was that it evolved. In the early 2000 there was an outbreak in North America and Europe with a new strain, the ribotype 027 strain which has evolved and adapted. Metronidazole resistance was higher; the strain had modified genetic structure permitting to produce much more toxins than the classic types and incorporated another binary toxin which role is still unknown[3,4]. First time discovered in 1980s it presented high resistance to fluoroquinolones.

METHODS

A comprehensive search using PubMed, Medline and Google Scholar without publication status or other restrictions was conducted.

Studies using comparaisons between different antibiotics, reviews of risk factors, case presentations and all sorts of guidelines were included. The main

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest
[2] Carol Davila University of Medicine and Pharmacy, Bucharest

objective of this paper was to review the main features and also to raise awareness of this health problem.

RESULTS

Diagnosis

Diagnosis is based on: clinical presentation, diagnostic tests, imaging and miniinvasive surgery.

The classical clinical exam reveals usually diarrhea in a patient with current or recent antibiotic use, frequent loose or watery stools. Occult blood or mucus may appear but melena or hematochezia are rare. Sometimes patients can develop colonic ileus or toxic megacolon. Both of them are very serious and unfortunately because of the ileus there can be no diarrhea so there can be a fatal delay in diagnosis. In this case diffuse abdominal pain, fever, abdominal distension are precious clinical signs. Finally there are those patients with very serious signs like septic shock or multiple organ failure.

All diagnostic tests have their strengths and weaknesses, the most used are EIA (enzyme immunoassays) for toxins A and B and then we have PCR, tissue culture cytotoxicity and assays for clostridial glutamate dehydrogenase (as a first line test).

Imaging unfortunately it is not specific for this kind of disease; still an abdominal X-ray or a computed tomography is of great value when we have to differentiate for other cases of occlusion or ileus.

There is another way of diagnosing the infection; still it holds a higher degree of invasiveness with all the secondary aspects.

We are talking about colonoscopies which can biopsy the membranes and solve the diagnosis in an ironclad manner.

Risk factors

Antibiotics

Multiple studies, some of them multicentric focused on what classes of antibiotics are involved in this disease. Most of them imply clindamycin, fluoroquinolones, cephalosporines(generations II, III, IV but not first generation). Rarely are cited also carbapenems and trimethoprim/sulphonamides, also peniclins seem to be involved[5].

Proton pump inhibitors and H2 antagonists

Normally they should be in same group but this affiliation is a bit forced. Proton pomp inhibitors are one of the most used therapies worldwide instead of H2 antagonists. Also there are some studies that recommend the use of H2 antagonists instead of proton pump inhibitors. Their role as a risk factor or not is not so clear. Some of them say that more than 2 days of proton pump inhibitor greatly increases the risk to develop C Difficile infection[6,7].

There are studies that demonstrated that one of those two protective agents can be administred concurentially with C Difficile treatment may it be metronidazole / vancomycin / fidaxomicin[8]. There are also studies that could not find any connection between the infection and the use of PPI[9].

Age> 65 years

This is one of the risk factors almost universally recognized. Almost all organisms at this age present somehow reduced turn-over, their innate resources are more limited so the immune response in this case is not so good, and the antibodies production rate is not so high so the host has lesser chances to suppress the infection.

Underlying illness

It is pure logic to assume that a weakened body would be more presumptuous to an infection. There are studies that associate this factor to the development of severe C. Difficile infections. In fact most of the studies at least agree to two of these factors respectively age and underlying illness.

In this category we include also neoplasia, gastro-intestinal surgery, naso-gastric tubes and gastro-intestinal disorders.

Long term hospitalization

This is also true for nursing homes. Both types of facilities present a high risk of infection given the high concentration of resistant germs and the difficulty to identify and isolate the infected persons. C Difficile is a spore type germ so the isolation is a must for the infected, and in this dormant form it can stay alive for months, so it is easy to assume the worst has passed[10].

The European Society of Clinical Microbiology and Infectious Diseases established a biochemical set of risk factors to predict an increased risk of developing severe disease[11].

1. Marked leucocytosis (leucocyte count >15 9 109/L)

2. Decreased blood albumin (<30 g/L)

3. Rise in serum creatinine level (≥133 lM or ≥1.5 times the premorbid level)

Treatment

For decades the only recognized and valuable tools were metronidazole and vancomycin. Both of them still stand as valuable medication.

A new antibiotic appeared a few years ago the fidaxomicin. As a last resort the infectionists use last tier drugs like Tygecycline.

Until 2009 there were no regulations for the treatment of this infection so there were a lot of medication schemes, some of them more or less efficient.

Fortunately nowadays there are international guidelines for the treatment of this infection. Less used substances have been tried some of them using great promise (Teicoplanin, Nitazoxanide, Rifaximin).

Tygecycline is a new glycylcyline from the tetracycline drug class. It has been shown to have activity against a wide variety of bacteria, including the antimicrobial-resistant strains. As with all tetracycline drugs, it is not recommended for pregnant or nursing women. One of the most important aspect especially for the urologic patient is that renal function monitoring is not necessary.

There are studies which compare vancomycin with fidaxomicin. Cure status are similar, however, fidaxomicin is associated with significantly lower recurrence rates than vancomycin for patients infected with non-NAP1 strains of C. difficile. For patients with the NAP1 strain, recurrence rates did not differ by treatment.

Emerging therapies

Toxin-binding resins and polymers and probiotics are two of the novel therapies which have been used in the treatment of this infection.

Unfortunatelly the results are still inconclusive, they are included in guidelines but not as a stand alone treatment but more as a adjuvant therapy[12].

As for immunotherapy, human monoclonal antibodies have been used with success, the main shortcoming is that the studies included few patients and we can not generalise the results. Still they show promising results some of them being in phase III trial.

In one of those studies at about 4 weeks after the resolution of symptoms the diarrhea reappeared. The question asked was if it was a relapse or the lifetime of antibodies just ran out and the organism was left defenseless[13].

European Society of Clinical Microbiology and Infectious Diseases

In case of non-severe infection (no signs of severe colitis) in non-epidemic situations and with CDI infection clearly induced by the use of antibiotics, it may be acceptable to stop the inducing antibiotic and observe the clinical response for 48 h, but patients must be followed very closely for any signs of clinical deterioration and placed on therapy immediately if this occurs.

Metronidazole is recommended as oral antibiotic treatment of initial CDI in mild/moderate disease.

There is insufficient evidence to support administration of probiotics, toxin-binding resins and polymers, or monoclonal antibodies.

Based on its pharmacokinetic properties vancomycin is considered superior to metronidazole in severe C. difficile disease.The use of high doses of vancomycin (500 mg orally four times daily) was included in the Infectious Diseases Society of America/Society for Healthcare Epidemiology of America treatment guidelines for management of severe complicated CDI as defined by the treating physician. However, there is insufficient evidence to support the use of doses >125 mg four times daily in the absence of ileus.

Fidaxomicin was not inferior to vancomycin for initial cure of CDI, but there are no data available on the efficacy of this drug in severe life-threatening disease.

Total abdominal colectomy should be performed to treat CDI in case of:
_ Perforation of the colon
_ Systemic inflammation and deteriorating clinical condition despite maximal antibiotic therapy; this includes the clinical diagnoses of toxic megacolon, acute abdomen and severe ileus. Colectomy should preferably be performed before colitis becomes very severe. Serum lactate may, inter alia, serve as a marker for severity (operate before lactate exceeds 5.0 mM).

A future alternative to colectomy may be diverting loop ileostomy and colonic lavage, combined with antibiotic treatment (intracolonic antegrade vancomycin and intravenous metronidazole).

Treatment of the relapse

There is evidence that suggests that vancomycin and fidaxomicin can be equally used in case of relapse. What is to be observed is that metronidazole is considered as a second line for the treatment of relapse.

In case of a secondary relapse or multiple relapses the medication conduit remains basically the same with some alterations of the alternative therapies.

DISCUSSIONS

This type of infection is usually an underestimated one. From the surgeon's point of view it may mean less but in our case the urologist must be very careful when dealing with this type of disease.

Not only most of the patients are > 65 years old but we must not forget that urinary sepsis is one of the most insidious ones, usually presenting with few symptoms and signs.

Being unable to diagnose fast enough the Clostridium Difficile infection usually is fatal for an old already surgically manipulated patient with lots of co morbidities.

Another problem luckily rare is the time to operate a patient with toxic colon. It is difficult to differentiate between the underlying surgical problem of the patient (may it be kidney, urether, prostate or bladder) and the acute onset of a colonic disease.

More, in these cases we find an ileus that is masking the underlying diarheea, making the moment to intervene very hard to choose.

It is very important for the urologists to be aware of this type of disease, to be capable of dealing with it and most important to recognize it fast enough.

SYSTEMATIC REVIEW

Article received on November 1, 2015 and accepted for publishing on November 19 2015.

Neuroendocrine differentiation in prostate cancer – a review

R. Popescu[1], Ovidiu Bratu[1,2], D. Spînu[1], D. Marcu[1], C. Farcaș[1], Marius Dinu[1], Dan Mischianu[1,2]

Abstract: Objectives: This review aims to provide practicing clinicians with the most recent knowledge of the biological nature of prostate cancer especially the information regarding neuroendocrine differentiation.

Methods: Review of the literature using PubMed search and scientific journal publications.

Results: Much progress has been made towards an understanding of the development and progression of prostate cancer.

The prostate is a male accessory sex gland which produces a fraction of seminal fluid. The normal human prostate is composed of a stromal compartment (which contains: nerves, fibroblast, smooth muscle cells, macrophages) surrounding glandular acins – epithelial cells.

Neuroendocrine cells are one of the epithelial populations in the normal prostate and are believed to provide trophic signals trough the secretion of neuropeptides that diffuse and influence surrounding epithelial cells.

Prostate cancer is the most frequently diagnosed malignancy in men. In prostate cancer, neuroendocrine cells can stimulate growth of surrounding prostate adenocarcinoma cells (proliferation of neighboring cancer cells in a paracrine manner by secretion of neuroendocrine products).

Neuroendocrine prostate cancer is an aggressive variant of prostate cancer that commonly arises in later stages of castration resistant prostate cancer.

The detection of neuroendocrine prostate cancer has clinical implications. These patients are often treated with platinum chemotherapy rather than with androgen receptor targeted therapies.

Conclusion: This review shows the need to improve our knowledge regarding diagnostic and treatment methods of the Prostate Cancer, especially cancer cells with neuroendocrine phenotype.

Keywords: prostate cancer, neuroendocrine cells, neuroendocrine differentiation

INTRODUCTION

Prostate cancer is the most frequently diagnosed malignancy in men, majority of them are adenocarcinoma (derived from transformation of the glandular cells) [1]. The prostatic glands are under the influence of androgens. Prostatic adenocarcinoma cells present androgen receptors and relies on androgens for development and progression. That's why standard therapies for advanced and recurrent prostate cancer is based on two principles: block androgen synthesis (chemical or surgical castration)

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

and inhibit androgen receptors [2][3].

Usually, this treatment provide clinical responses, but rarely eradicate all prostatic cancer cell populations and most patients after months/years develop resistance to these treatment – that means progression to castrate – resistant adenocarcinoma.

Neuroendocrine differentiation for most of the clinicians is associated with progression of prostate cancer to castrate – resistant disease.

NEUROENDOCRINE CELLS IN THE NORMAL PROSTATE

Neuroendocrine cells are found in many types of tissues, including in the normal prostate [4]. This cells secrete neuropeptides such as: serotonin, histamine, chromogranin A, calcitonin, bombesin, neuropeptide Y, vasoactive intestinal peptide, adrenomodulin [5],[6],[7],[8] and also growth factors (VEGF) [9]. The principal role is to maintain local homeostasis of the surrounding epithelial cells. Some of these neuropeptides have been found in seminal fluid, raising the idea that they may regulate sperm function [10][11].

Studies shows that neuroendocrine cells are present in all anatomic zones of the prostate and comprise less then 1% of benign prostatic glandular epithelium [12].

Neuroendocrine cells cannot be recognized on routine Hematoxilyn-Eosine staining. Ussualy this cells are found using immunohistochemistry with specific markers: chromogranin, synaptophysin, neuron specific enolase and CD 56 [13][14][15][16]. Other neuroendocrine cells markers reported in literature but not ussualy used in clinical practice include: cytochrome b561 [17], synaptic vesicle protein 2 [18][19], vesicular monoamine transporters [20].

NEUROENDOCRINE DIFFERENTIATION IN PROSTATE CANCER

Neuroendocrine prostatic carcinomas are often diagnosed on primary prostate needle biopsy with negative or low PSA level.

Neuroendocrine carcinoma of the prostate may be linked to resistance to androgen receptor signaling inhibition. Some prostatic tumors such as carcinoid tumor and small cell carcinomas are entirely composed by this type of cells with neuroendocrine differentiation. These tumors are aggressive and often present locally advanced or metastatic diseases with poor survival prognosis [21]. In general, these cells are negative for androgen receptor and PSA. Hormonal therapy is not effective while chemotherapy may have some value [22].

More frequently, prostatic tumors are composed by conventional adenocarcinoma with a small component of cells with neuroendocrine differentiation.

The neuroendocrine cells are indistinguishable from the normal adenocarcinoma cells on Hematoxilin-Eosine stained section under light microscope, and can be identified only by immunohistochemical stained using specific markers. Chromogranin A is the most used marker in clinical practice and is considered to be sensitive and specific [23].

Prostatic tumors with high grade or high stage and particularly in hormonal treated or hormone-refractory tumors, neuroendocrine differentiation is increased [24][25][26]. Also the level of serum chromogranin A are increased and is associated with tumor resistence to hormonal therapy [27]. In patients with hormone-refractory tumors, elevated serum chromogranin A level is predictor of poor prognosis, independent of PSA level [28].

NEUROENDOCRINE DIFFERENTIATION AND HORMONE-REFRACTORY PROSTATE CANCER

If the local curative treatments (radical prostatectomy, brachytherapy, radiotherapy) are no longer indicate for the patients with prostate cancer, androgen deprivation therapy is an effective therapy with significant symptomatic relief, suggesting that tumor growth is dependent on androgen receptors signaling. It is known that prostatic stromal cells support survival and proliferation of epithelial cells (paracrine secretion), that’s why, it is possible that neuroendocrine cells (who do not express androgen receptors and so are resistant to androgen deprivation) being capable to secrete neuropeptides and cytokines and so stimulate proliferation of adenocarcinomas cells. This situation suggest that androgen deprivation generally works, but eventually fails because neuroendocrine cells gradually substitute the function of stromal cells and so continued to stimulate the proliferation of prostate cancer cells.

Antibiotic resistant urinary tract infections in an urology ward

A. Rădulescu[1], Victor Mădan[1,2], A. Aungurenci[1], Ovidiu Bratu[1,2], C. Farcaş[1,2], Marius Dinu[1], Dan Mischianu[1,2]

Abstract: Introduction: UTI (urinary tract infections) represent a central pathology for a urological service. Antibiotic resistance is growing at a steady and alarming rate worldwide and especially in Romania.

Method and materials: We have analyzed all the patients that were admitted to our clinic for continuous hospitalization between January 2015 and October 2015. All patients undergone urine culture and all cultures positive had an antibiogram worked up. We have selected all patients that had antibiotic resistance to at least an antibiotic.

Results: From 1745 patients admitted for continuous hospitalization, we had 180 positive urine cultures at admission from which 125 had at least an antibiotic resistance.

Conclusions: Antibiotic resistance is a serious phenomenon, with potential lethal complications, which we encounter daily in urological practice

INTRODUCTION

Uncomplicated UTI are probably the most common urological condition. It is estimated that at least 1 out of 3 females will develop an UTI during their lifetime. UTI frequency at young females is associated with sexual intercourse. When urological malformations, pregnancy, menopause, urolithiasis occur conditions for recurrence of the disease are met. Recurrences are defined as at least 2 episodes of UTI in 6 months or 3 episodes a year.

Male patients develop UTI due to different mechanisms and at an elderly age. The most common mechanism that facilitates the development of UTI in men is bladder outlet obstruction caused mainly by prostatic enlargement.

UTI are caused mainly by Gram negative *enterobacteriacea*. Escherichia Coli is the cause for about 80-90 % of community acquired UTI's. In healthcare related infections E. Coli is still the leading cause but with a more modest percentage. Other pathogens that cause UTI are: Proteus mirabilis, Enterococous, Klebsiella pneumonie, Pseudomonas aeruginosa.

METHOD AND MATERIALS

Between January and October 2015, 1745 patients were admitted for continuous hospitalization in our Clinic. At admission all of these patients had their urine sent for culture.

The urine culture was tested for antibiotic response for the following antibiotics:

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

Trimethoprime-sulfamethoxazole, cefuroxime, cefotaxime, ceftriaxone, ciprofloxacine, ofloxacine, levofloxacine, gentamicine, ampiciline, oral penicillin, nitrofurantoine, imipenemcilastatin, ertapenem, meropenem and tigeciclin.

We had 180 positive urine cultures from which 125 were antibiotic resistant at at least one tested antibiotic.

We have analyzed the relationship between the germ and antibiotic resistance and also the sex and age of patients.

RESULTS

We had 180 positive urine cultures representing 10.31% out of all patients. 7.16% of all patients had at least one antibiotic resistance. 70% of the patients with positive urine cultures had at least one resistance.

Out of the 180 patients 104 were females (57,7%) and 76 were males (42,3%). Resistance was encountered in 56 females (44,8%) and 69 male patients (55,2%)

Out of all UTI's we had 143 E. Coli cases (79%), 25 Klebsiella pneumoniae (13,88%), 12 Proteus mirabilis (6,66%), 8 Enterococus (4,44%) faecalis and 2 cases with Pseudomonas aeruginosa (1,11%).

In the antibiotic resistant group we encountered the following bacterial involvement: 88 patients had E. coli, 19 had Klebsiella pneumoniae, 10 had Proteus mirabilis, 6 had Enterococus faecalis and 2 had Pseudomonas aeruginosa.

The decreasing percentage of antibiotic resistance was the following: Psedomonas aeruginosa cases had 100% resistance at at least one antibiotic, 83% of Proteus mirabilis cases had resistance, 76% of Klebsiella cases had resistance, 75% of Enterococus faecalis had resistance while the least resistant germ was E. Coli with 61,53%.

There were no significant differences between sexes except the fact that all the 2 cases with Pseudomonas aeruginosa were registered at male patients with long time users of indwelling ureteral catheters.

Regarding antibiotic resistance we had only 2 cases(1 case with Pseudomonas and 1 case with Klebsiella) which had no sensibility to any of the tested antibiotics. The strongest resistance was registered to ampicllin meaning that 115 (92%) cases with resistance had no sensibility to the drug. Resistance to penicillin was counted at 97 (77%). Third highest resistance was encountered to Thimetoprim with 90 patients (72%). The lowest resistance was registered for imipenem cilastatin, ertapenem, meropenem and tigeciclin. With only 2 cases (1,6%). Levofloxacin had also low resistance with 25 cases meaning 20%.

CONCLUSIONS

Antibiotic resistance is real threat to the general health of humanity, being more and more encountered especially in hospital related infections but also in community acquired infections. UTIs make no exceptions. Romania is especially at high risk with reported resistance to quinolones exceeding 30%.

The data we obtained from patients admitted for continuous hospitalization in our Clinic is similar to data in international literature reports concerning antibiotic resistance. It is important to realize the fact that urological patients are at high risk of developing antibiotic resistant infections due to the age profile, the pathology and the increasing number of indwelling catheters.

Complications of radical retropubic prostatectomy – our experience

Ovidiu Bratu[1,2], D. Spînu[1,2], I. Oprea[1], R. Popescu[1], D. Marcu[1], C. Farcaş[1,2], Marius Dinu[1], Dan Mischianu[1,2]

Abstract: Introduction: Radical retropubic prostatectomy represents in its various forms (open, laparoscopic and robotic) the "gold standard" treatment for adenocarcinoma of the prostate. Unfortunately like al treatment solutions it has its shortcomings.

Retropubic radical prostatectomy, external beam radiation therapy and brachytherapy are the curative options.

Materials and Method: The experience of Clinic of Urology from Central Military Hospital representing more than 100 cases was analyzed . Classical open retropubic prostatectomy was performed in all cases.

We focused in this paper on intraoperative complications and also precocious and late postoperative complications.

Results: Our results are matching the other centers in terms of intraoperative complications (blood loss), early postoperative complications (hematuria, urinary tract infection, lymphatic drainage) or late postoperative complications (erectile dysfunction and urinary incontinence). However none of these complications are to be underestimated

Conclusions: The limits of this intervention can be pushed a litle bit further, in our opinion the age factor is a relative one, some of these patients having a longer than 10 years life expectancy. It provides good oncological outcome with manageable complications most of the times.

Keywords: radical retropubic prostatectomy, complications, nerve sparing

INTRODUCTION

Prostate cancer is nowadays the second most frequent neoplasia in men. Most probably the reason for this frequency is the presence of PSA as a valuable diagnosis tool and also the existence of the guidelines.

Also the very aggressive policy of controls for all men after 50-55 years has begun to show its results. Although radical prostatectomy, radiotherapy and brachytherapy are almost equal in terms of oncological results, in psychological, financial, and why not life quality radical prostatectomy is represented better.

MATERIALS AND METHOD

We have analyzed our experience at the Central Military Hospital regarding radical prostatectomy between January 2009 and February 2015. Our surgical teams carried on during these period more

---

[1] Carol Davila Central Emergency Military Hospital, Bucharest

[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

than one hundred radical prostatectomies for patients with localized or advanced prostate cancer. This paper focuses on intra and post - operative complications we encountered[1,2].

Patients mean age was 63.09 years ranging between 51 to 78 years of age. We haven't taken into consideration the general life expectancy for men in Romania, moreover the general biologic status was considered as inclusion criteria.

Major diagnosis criteria for prostate adenocarcinoma were: anamnesis, total PSA and free PSA levels, digital rectal examination and transrectal ultrasonography, which was usually performed when prostatic biopsies were obtained[3,4].

Medium prostatic volume of 45 cc without taking into consideration patients that prior have benefited of endoscopic surgery.

PSA levels varied between 0.5 ng/ml and 24 ng/ml. Two cases presented with PSA levels above 20 ng/ml. Those two patients were classified postoperative as pT3b – locally advanced.

Mean Gleason score, which is an important prognosis factor, was between 5-7 at 84 patients. Low risk prostate adenocarcinoma was recorded in six cases, ten patients with Gleason 8 were included in high risk and very high risk groups Patients diagnosed with Gleason 9 score were unsuitable for surgery.

In accordance with European Guidelines surgery was performed at six to eight weeks after the transrectal biopsy and 12 weeks after the transurethral resection of the prostate in order to to reduce the prostatic inflammation. General anesthesia was chosen for all patients.

Pelvic lymph node dissection was performed at almost all patients. We used extended lymph node dissection when patients were included in high or very high risk groups.

Urethro-vesical anastomosis was realized using four to eight resorbable sutures excepting six cases when no sutures could be placed due to the short urethra left after the prostatic excision. Those six cases were managed by gentle traction of the urethro-vesical catheter and maintaining the catheter for 14 days compared to 7 to 10 days as we did on the other cases.

RESULTS

The most redutable intraopearatory complication we encountered was blood loss which ranged between 400 milliliters and 2500 milliliters. Twenty - two patients needed intraoperatory blood transfusions.

Early complications included: gross hematuria (eight cases) which spontaneously remitted in 24 to 48 hours, wound infection (six cases), prolonged lymphatic pelvic drainage (sixteen cases), urinary tract infection (twenty cases), pulmonary embolism with subsequent death of the patient (one case).

Eighteen patients developed moderate or severe LUTS caused by bladder neck sclerosis or urethral stricture which was managed trough endoscopical procedures in the first year post-op. Four cases developed urinary fistula during the first 72 hours after prostatectomy three needing surgery in order to perform a new urethro-vesical anastomosis and one being resolved by placing a gentle traction on the urethro-vesical catheter for 24 hours.

Late complications recorded were urinary incontinence and erectile dysfunction. Following data were analyzed at one year after the surgery, only 78 patients being included in the evaluation. Urinary incontinence was evaluated by the number of pads used by the patient.

Almost 80% confirmed that they do not use any incontinence pads. Ten patients use only one pad a day and lose urine only when changing positions or when sneezing or coughing. Three patients affirmed moderate urinary incontinence using 2-3 pads a day[5].

We used a similar technique like the TOT used for women to place a suburethral transobturatory mesh for eleven ot if the thirteen patients with urinary incontinence with very good results and lack of symptoms in nine cases.

Using Walsh technique neurovascular bundles were spared in 62 patients. Erectile function, a very important part in quality of life was assessed using anamnesis and standardized questionnaires. 68.42%

(26 out of 38 patients) of the patients with surgical bilateral neurovascular bundles preservation affirmed satisfactory erections while only 33% (eight out of 24 patients) with unilateral bundle preservation affirmed satisfactory errection[6].

In sixteen cases due to oncological reasons or intraoperative bleeding neurovascular bundles were not preserved. All patients that benefited from the nerve sparing technique surgery were set on low dose daily 5 PDE inhibitors.

CONCLUSIONS

Radical prostatectomy is the standard treatment for localized and in some cases of locally advanced disease. We consider biologic status to be a more reliable indicator than age alone. That being said we consider far better to evaluate the patient before judging only the age.

Surprisingly one of the most bothering complications we encountered was bladder neck sclerosis; in this case one of the patients had undergone endoscopic surgery for three consecutive times. One of the hypotheses is the using of tension on the urethro-vesical catheter consequent bladder neck ischemia and in a secondary time sclerosis. This was not the case of this patient.

Intraoperative bleeding remains one of the most serious problems also because of the underlying co morbidities which may be aggravated during surgery.

Incontinence is a very bothersome late complication. Psychologically it has a great impact on the patient quality of life; actually along with erectile dysfunction those two are considered to be the highest burden from the patient's point of view. Still the existence of TOT like procedure for men offers an efficient solution to this problem.

Scintigraphic evaluation of the kidney

Iulia A. Chiriac[1], Raluca M. Mititelu[1], Cătălin Mazilu[1], Olga Niculescu[1], Mihaela G. Lepuş[1]

Abstract: *There are more than one technique used to evaluate the kidney, besides the standard ultrasound, computed tomography (CT), and magnetic resonance imaging (MRI), there is also renal scintigraphy. The renal nuclear medicine procedures are grouped as in vitro (urine counting wells, basic probe detectors for clearance studies) and in vivo procedures (static and/or dynamic examinations done with planar gamma cameras, and single-photon emission computed tomography (SPECT) to determine kidney parameters or for cortical imaging). Renal scintigraphy has been a useful tool, since the early 1950s, in the diagnosis and management of many pathological changes in the kidney, especially in measuring renal function (e.g. obstructive/nonobstructive uropathies, renal inflammatory diseases, tumours, renal hypertension, and renal transplant viability). [1]*

INTRODUCTION

The radionuclide investigation of the kidney includes detection of renal afflictions and measurements of quantitative indices that estimate the renal perfusion and function. Ultrasound and computed tomography are commonly used for the evaluation of renal structural anatomy, and the role of nuclear renal imaging is more for functional analysis, less in anatomical imaging (e.g. cortical imaging).[1,2]

Renal scintigraphy, also known as a "renal scan" or "renal radionuclide imaging" or “renography” includes various investigations that use different radioisotopes to evaluate renal blood flow, renal split function, and the renal excretion performance of both. It yields specific and often unachievable information by using other imaging procedures. [2]

Clinical indications for renal scintigraphy (adapted from *Nuclear Medicine: The Requisites*, 4th ed)**:** [3-5]

1. Blood flow abnormalities
2. Function quantification (reduced performance of one or both kidneys)
   a. Differential function
   b. Glomerular filtration rate (GFR), effective renal plasma flow (EPRF)
3. Cirrhosis of the kidney(s)
4. Differentiation between a mass lesion and a column of Bertin
5. In infants with abnormalities of the urinary tract to study the urinary flow
6. Obstruction: ureteropelvic junction, ureteral
7. Pyelonephritis: both acute and chronic tubule-interstitial nephritis and parenchymal scarring
8. Renal failure: acute and chronic
9. Renal artery stenosis with/without renovascular hypertension
10. Renal vein thrombosis
11. Surgical:

---

a. performance assessment before operations in the case of chronic diseases (e.g. diabetes)
b. Renal allographs: for clinical monitoring of renal function, transplant rejection or other complications, transplant anastomosis assessment
12. Trauma

PURPOSE

The purpose of this paper is to provide a better understanding about dynamic renal imaging in several kidney pathologies, with an emphasis on obstructive renal pathology and to clarify the meaning of some quantitative parameters used in renal scintigraphy.

MATERIAL AND METHODS

Nuclear renal scans are various, complex and also a subject to institutional preferences, that is why a standardization of the techniques is hard to achieve. All nuclear renal procedures have some basic common conditions that must be taken into account before, during and after patient examination. First of them involves the intravenous bolus injection of a renotrophic radiopharmaceutical (a medicine marked with a radioisotope) that emits a small amount of radioactivity into the patient. Usually, the radiotracer administered to the patient is well tolerated, with no systemic toxic effects. Some mild-moderate allergies or adverse reactions (such as dizziness, headache, metal taste, flushing) are extremely rare reported. The radiation dose is relatively low, less than the standard chest x-ray. The examination is performed with the patient either lying on the examination table, in the supine position, or standing. [3-7]

The pre-scan preparatory measures that are common are hydration, about 30 minutes prior to the actual examination, the patient should drink about 1 litre of fluid, and an empty bladder, the patient should void before examination. [3-7]

It is of great importance that in the last 3-6 months prior to the renal scintigraphy, no high doses of iodine substances to be taken, like x-ray and CT contrast agents, or certain medicines (e.g. Amiodarone) because the results could otherwise be distorted. [3-7]

In general, chronic therapy medications should not be discontinued prior to the exam. For specific problems, specific blood pressure lowering drugs (ACE inhibitors, diuretics) must be mentioned to the nuclear medicine physician as there is a period of drug abstinence in some cases. [3-7]

Different scanning protocols with various radiopharmaceuticals are available for scanning the kidneys. Choosing the right technique and optimal radiopharmaceutical depends on the patients' medical history, clinical setting and indication. [3-5, 8]

Plenty and divers radiopharmaceuticals have been produced in the last 60 years to assess renal function; some are used in laboratory assays by measuring blood samples and determining the renal clearance of the radiopharmaceutical and others for dynamic or static studies with a gamma camera or a SPECT system. The gamma cameras and SPECT systems monitor the passage of radiopharmaceuticals through the kidney and urinary tract by registering and processing of the emitted gamma radiation. [9, 10]

The radionuclide agents usually used for determining renal function and anatomy can be grouped into three main categories [5,8]: those filtered by glomerular filtration, those excreted by tubular secretion via proximal tubule receptor-mediated endocytosis from the glomerular filtrate, and those retained in the renal tubules for long periods, useful for cortical imaging. [8]

The most frequently used radiopharmaceuticals in renal scintigraphy are illustrated in Table 1.

Table 1. Most frequently used renal radiotracers

Glomerular Filtration (GF)	• Tc-99m diethylenetnamine pentaacetic acid (Tc-99m DTPA) • 99mTc-mercaptoacetyltriglycine (Tc-99m MAG3) • I-131/I-123 orthoiodohippurate (OIH)
Tubular Secretion (TS)	• I-131 OIH • Tc-99m MAG3 • Tc-99m ethylenedicisteine (Tc-99m EC)
Tubular Filtration (TF)	• Tc-99m dimercaptosuccinic acid (Tc-99m DMSA) • Tc-99m glucoheptonate (Tc-99m GHA)

Table 2. Renal radiotracers excretion mechanisms (adapted from *Semin NM Apr.92*)

	GF	TS	TF
Tc-99m DTPA	>95%		
Tc-99m MAG3	<5%	95%	
I-131 OIH	20%	80%	
Tc-99m GHA	40%-60%		20%
Tc-99m DMSA	some		60%

There are four important types of renal imaging methods obtained by using a planar gamma-camera or a SPECT system in order to evaluate whether the kidneys are working normally or abnormally:

- Renal perfusion and renal function imaging are dynamic studies with images taken in series, over a period of 30 minutes immediately after the bolus radiotracer injection and determines the blood flow distributed to the kidneys, recognizes a potential narrowing of the renal arteries, and helps in determining the kidneys functioning. [2, 11]

- Diuretic renal scintigraphy is used to detect kidney obstruction. The procedure is similar to the renal perfusion, and seriated images are taken before and after the introduction of a diuretic (in the 15th minute of acquisition) to help urine elimination from the kidneys. [2, 11]

- ACE-inhibitor renal scintigraphy utility is in detecting renovascular hypertension, not renal artery stenosis, by comparing renographic images before and after taking an ACE-inhibitor. [2, 11] It is also a dynamic study and the image acquisition process begins when the radiotracer is injected intravenously in bolus. [3-5, 8, 10]

- Cortical renal scintigraphy is a static study and detects the amount of normal functioning kidney tissue. [2, 11] After the tracer administration, there is a three hour delay before the imaging acquisition can begin. [3-5, 8, 10]

Generally the dynamic renal functional studies are acquired in two parts. The first part evaluates the renal blood flow, which is calculated in the first pass of the radiopharmaceutical bolus through the abdominal aorta and renal arteries. The second part assess the kidney uptake and clearance function over the next 25 to 30 minutes of acquisition. [3-5, 8, 10]

GFR and EPRF are important kidney function markers evaluated by dynamic renal scintigraphy. Normal GFR varies in accordance with age, sex, weight (nutritional status), diet, race, and kidney size, which is proportional to body surface area. [12, 13, 14] The estimated GFR is calculated using these factors and the serum creatinine value, but it is not helpful when there are unilateral changes or when kidney function is very abnormal. Unilateral renal function changes are difficult to identify with other imaging techniques, but easy to determine with camera-based renal scan split functions. The percent differential function (split function) calculates the contribution of each kidney to the renal function and can be applied to GFR or ERPF data. [3-4, 15]

Nuclear techniques are not 100% “accurate” in measuring kidney function (GFR, ERPF), but are superior to investigations based on the serum creatinine value. [3, 14] Using renal scintigraphy patients can be followed over a long period of time, because this technique is highly reproducible in any one patient. [3, 13, 14]

Table 3. Renal radiotracers used for renal function measures
(adapted from *Requisites of Nuclear Medicine 4th ed*)

Effective Renal Plasma Flow (ERPF)	Tc-99m MAG3 I-123 / I-131 OIH H-3 or C-14 paraamino-hippurate (PAH) I-125 or I-131 iodopyracet
Glomerular Filtration Rate (GFR)	Tc-99m DTPA Cr-51 EDTA I-125 diatrizoate I-125 iothalamate C-14 or H-3 inulin In-111 or Yb-169 DTPA Co-57 vitamin B12

The Tc-99m DMSA cortical scan is used to evaluate renal cortical lesions in patients with suspected pyelonephritis, to detect renal scarring in a patient with reflux, and, in some occasions, to differentiate a prominent column of Bertin from a tumorous formation. Renal cortical scintigraphy provides additional information by showing changes and improvements over time, that are impossible to evaluate with conventional structural and anatomical imaging modalities, like ultrasound, CT, and MRI. [3, 13, 14]

RESULTS

The images obtained with the gamma camera should be inspected after acquisition in order to evaluate if the examination was done in proper conditions. After visual inspection the image data is processed and regions of interest (ROIs) are defined over the kidney and surrounding background so that the renogram curves can be generated. [5, 7]

The time-activity curve (TAC) represents a graphic illustration of the renal function and is composed of 3 parts: initial rise, upslope and downslope. The first part reflects the radioactivity that arrives via the renal artery to the kidney. The upslope (ascending limb) reflects kidney uptake before the radiopharmaceutical begins to be excreted by the kidney (the descending limb). The peak time accurately indicates the point at which the extraction and accumulation trend is reversed to the evacuation process. [5, 7]

This curve is important in diuretic renal scintigraphy. Diuresis renography helps to discern between obstructive (calculus) and nonobstructed dilated urinary tract, and in the postsurgical evaluation of the renal system function and urodynamic. Acute obstructive uropathy is a commonly encountered condition. When unilateral obstruction occurs the changes in the measured renal function are a little decrease or imperceptible, but the bilateral form can result in significant kidney function losses. [5, 16]

The radionuclide renogram TAC provides an accurate graphic illustration of the dynamics of urinary excretion. In obstructive uropathy a calculus can give various degrees of hydronephrosis, depending on the site in which it is lodged. In the case of acute obstruction due to a renal calculus, pressures increase fast in the pyelocaliceal system and in the ureters above the point of obstruction. The affected kidney has a characteristic aspect: a dilated urinary tract with a thin cortex, and it shows on the TAC a slow continuous accumulation of tracer in the collecting system, a slow increasing ascending curve with no downslope. In contrast, the opposite kidney, which has a normal function and no obstruction, will show a good uptake and excretion, and the three part TAC. [7, 17]

In some cases the calculus produces a partial obstruction of the urinary excretion pathways. In order to demonstrate this a diuretic like Furosemide is administrated at various times during the course of the renal scan. The decreasing aspect of the curve after the administration of the diuretic indicates an incomplete obstructive pattern (as in Curve 3), and as for the rising curve a complete obstruction (as in Curve 2). [7]

Figure 1. Time activity curves
(adapted from *EANM: Dynamic renal imaging in obstructive renal pathology. A Technologist's Guide*)

QUANTITATIVE INDICES

Renal perfusion is evaluated by visual and quantitative analysis (1- to 3-second images) of the initial bolus as it transits the abdominal aorta and enters the renal arteries (used in renal number anomalies, renal transplant). [10, 11]

Relative Function represents the relative uptake of the radiopharmaceutical for the evaluation of uni-/ bilaterally impaired kidneys. [10] The split function is particularly useful because estimated GFR and serum creatinine may not identify unilateral lesions. [3]

Renal Size. Several chronic renal diseases will result in bilaterally small kidneys, whereas the kidneys may be bilaterally enlarged in early diabetic renal disease, acute interstitial nephritis, HIV nephropathy, and amyloidosis. The resolution of structures of the renal parenchyma with nuclear medicine may not be as clear as with other imaging techniques, such as CT or MRI that is why nuclear renal images are not usually used to differentiate between cysts and tumours. [10, 11, 18]

The time to peak, or T max, refers to the time from radiopharmaceutical intravenous administration to the peak height of the renogram curve. 99mTc-MAG3, 99mTc-DTPA and OIH renograms normally peak by 5 min and drop to half-peak value until the 15th minute after injection; however, in some cases, physiologic retention of the radiotracer in the renal calyces or pelvis can alter the aspect of the TAC in normal kidneys and lead to prolonged values for the time to peak, 20-min/ maximum count ratio, and T½. [8, 10, 19, 20]

Time (mins)

The T½ represents the time is necessary for the radioactivity in the kidney to drop to 50% of the maximum value (time to peak, or T max); this index is important in diuretic renography for patients with suspected urinary tract obstruction. [8, 10, 19]

The 20-min/maximum count ratio is an index of the transit time and a measurement of residual cortical activity, the ratio between the kidney counts at 20 min to the maximum (peak) radioactivity; it is useful in monitoring patients with suspected urinary tract obstruction and for detecting renovascular hypertension. [8, 10, 19]

CONCLUSION

Renal radionuclide studies are versatile procedures and vary depending on institutional preference, clinical setting of the patient and medical indication.

Renal scintigraphy is a complex subject and understanding some basic principles, the use of radiopharmaceuticals available to image the kidney and monitor its function, the quantitative indices that can be generated and protocols can be useful for the physicians specialized in nephrology and urology in evaluating patients with diseases of the urinary tract and renal physiology.

Penile prosthesis – a viable solution for erectile dysfunction refractory to conservative therapy

D. Marcu[1], Ovidiu Bratu[1,2], D. Spînu[1], A. Rădulescu[1], C. Farcaş[1,2], Dan Mischianu[1,2]

Abstract: Introduction: Erectile dysfunction(ED) is a serious condition which can affect men of all ages, with an important impact over the quality of life. When conservative therapy fails, a viable solution is the penile prosthesis implantation (PPI).

Objective: The purpose of this paper is to present data from recent literature regarding the satisfaction rates of men who have undergone penile PPI and as well as the partners satisfaction rates, ease of use, informations regarding long term survival of these prosthesis, postoperative complications and long distance complications, the effectiveness and the way that penile prosthesis have influenced the quality of life of the men who have opted for this solution.

Material and methods: We have analyzed recent long term studies concerning the outcomes of the PPI, studies which were made retrospectively, over a period of time of 10 to 15 years.

Results: Compared with the conservative treatment for ED, the satisfaction rates achieved after penile prosthesis implantation are higher. According to these studies, the overall patient's satisfaction is 70-90%. The difference between patient and their partners' satisfaction rate is negligible, this difference ranging between 2 to 8%. The satisfaction rate regarding the adequate erection for sexual intercourse is 80-90%. The overall satisfaction rates for the malleable prostheses are lower compared with inflatable devices, 30-75%, respectively 75-90% for the inflatable prosthesis. The mechanical and overall survival rates for the malleable prosthesis range between 65-80% at 10 years, and 58-75% for the inflatable devices. Overall ease of use is rated as 78%. Complications after implantation can be encountered in less than 5% of cases and infections in less than 2%. The likelihood of continued use is higher in the group of the patients with the inflatable prosthesis compared with the malleable ones 70-80%, respectively 50-60%. Up to 85-90% of patients with inflatable prosthesis would recommend them.

Conclusions: PPI is a high effective treatment for erectile dysfunction, refractory to pharmacological treatment. The inflatable penile prosthesis (IPP) provides more overall satisfaction than the malleable ones. The patients with IPP are more likely to continue using their devices than those with the malleable prosthesis. PPI improves significantly the quality of life for patients with erectile dysfunction.

INTRODUCTION

Erectile dysfunction is defined as the inability to obtain and maintain an erection with sufficient penis rigidity, adequate for successful sexual contact. Although ED decreases significantly the quality of life for both men and their partners, in many countries

[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

ED is understated because of cultural aspects.

ED can affect men of all ages, but as life expectancy continues to increase, so does its prevalence. It is estimated that the prevalence of ED in men over the age of 50 years is higher than 50 percent, and this prevalence grows as the age increases. This condition is not exclusively encountered in men over the age of 50. It is estimated 3-5 percent of young men with ages between 15 and 25 years may suffer from this condition and 7 to 10 percent of those with ages between 25-45 [1].

Despite initial beliefs that the most common cause for ED was the psychological factor, especially in young men, it is now proven that organic causes are responsible for 70 to 90 % of ED. There are several proven pathologies proven in ED [2]:

a) Diabetes Mellitus-is a frequent cause of ED. Men with DM compared with general population may have ED at an earlier age. The prevalence of ED in the population of men with DM can be as high as 70-80%. The peripheral polineuropathy, microangiopathy and arterial insufficiency encountered in DM evolution can explain the earlier age of ED appearance and a higher prevalence than individuals without DM [3].

b) Vascular causes-atherosclerosis plays an important role in ED physiopathology. The presence of aortic or iliac atheromatosis can decrease the blood inflow, thus explaining the ED prevalence of up to 50 % in patients with atheromatosis. Another vascular cause may be the increased venous outflow, which depends on the trabecular smooth muscle relaxation and on the erectile tissue’s capacity of expandability.

c) Iatrogenic causes responsible for ED- renal transplantation, aortic or peripheral surgery, abdominal perineal resection of the rectum, perineal irradiation, cystoprostatectomy or radical prostatectomy (RP). Erectile dysfunction secondary to cystoprostatectomy and radical prostatectomy may be encountered in up to 80% of cases. Since the nerve sparing RP was introduced by Walsh over years ago, the incidence of ED was decreased to 40-60% [4]. The incidence of ED post RP depends on patient age, comorbidities, preoperative potency status, type of surgery, surgical technique (open, laparoscopic or robot assisted RP), surgical experience, extensive nerve sparing (unilateral or bilateral) [5]. Although some patients believe that radiotherapy may be associated with a lower risk of ED, it has been proven that ED may be encountered in 20-80% of patient who has undergone radiotherapy. Studies have shown that the incidence of cavernosal fibrosis and ED are similar between RP and radiotherapy [6,7].

d) Trauma – pelvic fractures may affect the internal pudendal or common penile artery or the neurovascular bundle.

e) Endocrinological causes such as: hypogonadotripic hypogonadism, hypergonadotropic hypogonadism, hyperprolactinemia and hyperthyroidism.

It is known that testosterone increases sexual interest and the frequency of sexual acts, as well as the frequency of nocturnal erections, but it’s role on visual or fantasy induced erections is little to none.

f) Neurological causes:
- CNS: Parkinson’s disease, encephalitis, temporal lobe epilepsy, stroke, multiple sclerosis (50-70% of patients with MS may have ED), tumors, myelodisplasia;
- periphereal nerves (trauma, diabetic polineuropahty, alcoholic neurophathy and radiopelvic surgery).

g) Penile diseases: Peyronie’s disease, trauma, priapism (vascular lesions).
h) Drugs: Marijuana, Opioids, Ethanol, Antimuscarinic drugs, Antihistamine, Tricyclic antidepressants, Estrogens, Spironolactones, Ketoconazole, and many other drugs.
i) Renal failure-up to 40-50% patients on dialysis suffer from ED.

TREATMENT

Currently there are three lines of treatment for ED. The first line and the most used one is oral medication, especially phosphodiesterase 5 inhibitors. Since 1998, when the first PDE-5 inhibitor was introduced, Sildenafil (Viagra), the management of ED was revolutionized due to its high efficacy and few adverse effects. As time passed other drugs with higher efficiency and superior safety profiles became available, such as: Vardenafil (Levitra) and Tadalafil (Cialis). These drugs block the hydrolysis of cyclic GMP, increasing the accumulation of GMPc and potentiating the effect of NO [2]. For many men the treatment with PDE-5 inhibitors has allowed them to regain normal sexual function and regain self-confidence.

The second line treatment is the intracavernous injection of vasoactive drugs such as papaverine, prostaglandin E1 or phentolamine. The efficacy of this therapy is high, but the pain and the risk of ischaemic priapism limit its utilization [8]. The third line of treatment is the surgical implantation of a penile prosthesis. When the conservative therapy fails(PDE 5 inhibitors, intracavernosal injections, vacuum erection device, intraurethral suppositories with alprostadil – Is a PGE1 which increases corporeal oxygenation by promoting blood inflow) or when the patients are reluctant to any form of conservative therapy, the solution is the penile prosthesis implantation. The first penile prosthesis were introduced at the beginning of the 1970s . Since then they have been greatly improved and the surgical techniques for placement have evolved and made penile prosthesis implant a very effective treatment for ED [9]. This kind of treatment is effective and safe, and it also offers high satisfaction rates for patients and for their partners. With the technical improvement the number of complications and revision surgeries decreased, thereby the popularity and use of penile prosthesis for the treatment of ED increased.

The penile prosthesis available on the market include the one piece malleable and the two or three piece inflatable versions, each type of prosthesis having its own advantages and disadvantages. Malleable prosthesis is easier to use and have fewer mechanical problems compared with the inflatable prosthesis and they are also less expensive. The disadvantage of malleable implants is that complete penile detumescence cannot be achieved and this may be an important factor for patient unsatisfaction [10]. The inflatable prosthesis permit flaccidity and have a better functional result, but not all patients have the dexterity to use them, especially older men. Despite the implantation of penile prosthesis has been well documented, many urologists are reluctant to this form of treatment in older patients, due to the concern that older men have less dexterity and ability to operate an inflatable device [11]. The patients' satisfaction regarding the penile prosthesis implant is associated with their expectations and the performance of the implanted prosthesis [12]. Therefore, the decision regarding the type of prosthesis should be made by the doctor and by the patient, during a discussion where the doctor explains the advantages and disadvantages of every type of prosthesis, the risk of complications, the rate of satisfaction and unsatisfaction that both patient and his partner may have from this type of treatment, thus making sure that the patients will have expectations in line with reality.

The three piece inflatable penile implants are currently the most used prosthesis and their results regarding patient satisfaction are very good. The malleable and two piece penile prosthesis can be used in selected cases, where the three piece prosthesis has questionable indications (like in the case of elderly men who may have low dexterity and ability to operate such devices) [13,14].

Partners' satisfaction is questionable because few studies have investigated this problem during a long term follow-up period; although in literature the rate of partners' satisfaction is similar with men satisfaction. For more realistic results regarding this problem, evaluating the two partners separately during the follow-up period should bring out interesting results (in line with reality) [15].

Hakan Kilicarslan et. al in a recent study regarding the comparison of patient satisfaction for the malleable prosthesis (AMS 600-650) and two piece inflatable penile prosthesis (AMS Ambicor) concluded that the two piece inflatable prosthesis was found to be more successful and more likely for continous use when compared to the malleable device. A total of 72 patients had either AMS 600-650 or AMS Ambicor, but only 46 patients were reviewed during a long time follow-up. The percentages of patients with AMS 600-650 who reported to be satisfied, very satisfied and unsatisfied after the implant were 34,78% (8 patients out of the total of 23 questioned after the operation), 30.43% (7 patients out of 23) and 34,78% (8 patients out of 23). For the patients with the two piece inflatable penile prosthesis the results were: 73.91% (17 out of 23), 13.04% (3 out 23) and 13.04%. The percentages of patients who reported to be very likely, unlikely or very unlikely to continue using the malleable implants were: 30.43% (7 patients), 34.78% (8 patients) and 34.78%; in the case of the patients with the two piece inflatable devices the results were: 65.21%, 21.33% and 13.04% [16].

A study made by Natali et. al revealed that the likelihood of continuous for the two piece device AMS Ambicor was 89% (59 patients) and for the malleable device AMS 600-650 was 56% (9 patients) [13].

In another comparative study Lux et. al reported that the partners satisfaction rated 79% with the two piece prosthesis [17].

Levine related an overall satisfaction rate of 90% for men and the 82% for their partners, of a total of 131 patients, patients which benefited from the AMS two piece Ambicor implant [18].

Minervini reported that the 71% of patients using the malleable AMS 600-650 were satisfied with the implant [19].

Yoon Seob Ji in a study made on 74 patients who underwent implantation of inflatable penile prosthesis reported that the overall satisfaction was 86,8% and that 81,1% said that the prosthesis improved their sexual life. 83% of the patients in the study would undergo surgery again and 88.7% would recommend it to a friend. Only 60.4% of the patients interviewed during the follow-up period reported that they had an orgasm [20].

Mario Paranhos and collaborators established that 86.3% of patients (120 patients questioned out of 249 operated) rated their satisfaction after the implant as good, excellent or very good. The partners' satisfaction percentages was similar. The follow-up period was 40 months [21].

Humberto G. Villarreal and LeRoy Jones, in a study about penile prosthesis in the elderly men, reported that overall satisfaction was 4.3 (from a scale of 1 to 5, 5 meaning very satisfied), the ease of use was 4.1 (from a scale of 1 to 5.5 meaning very easy) and the mean use was 3,3 per month (0 to 7 times a month) [11].

Carson and associates evaluated satisfaction rate in 372 patients, group in which was used the AMS 700 CX prosthesis and it was stated that 79% used this prosthesis at least twice a month and that 88% would recommend the prosthesis for a friend [22].

There was little data regarding implantation of penile prosthesis in elderly people. As the life expectancy and longevity continuous to increase so does the ED problem refractory to first line treatment. Accordingly to Lindau, elderly couples remain sexual active even into the eight decade of life [23]. So the number of elderly men seeking penile prosthesis implantation will have a significantly increase. There are numerous potential complications of the inflatable penile prosthesis such as surgery related complications (haematoma, infections, erosion of the corpus cavernosum and even perforation) and mechanical failure (reservoir leakage, cylinder leakage, pump failure) [14,24].

The incidence of these complications depends on the follow-up period. In the immediate postoperative period, Paranhos stated that 24.5% patients reported pain, 7,9% had local infections and 8,6% had other complications such as wound dehiscence, difficulty voiding or local secretions without infection. In regards to late complications 8.6% of patients had to undergo revision surgery (12 patients out of 139 operated and followed up), of whom 4 the prosthesis had removed due to inefficacy and 8 had them exchanged. 2 of the 8 patients who had them exchanged had prosthesis fractured, 4 had inadequate size and the other 2 had extrusion of the cylinder. He remarked in his study that the risks of complication for the patients that have had radical prostatectomy previously was higher, 3,3 times higher. The rate of postoperative infections in this study was 7.9%. Paranhos explains that this high rate of infections compared to other studies is due to the experience of medical trainees, the high number of surgery in the operating rooms and the economic and social conditions of the patients [21]. The rigorous preoperatory asepsy has shown to reduce the incidence of infection to 4% from initial overall rate of 12% [25].

Jarow et. al [26] reported an infection rate of 1,8% and Gower a rate of 2.1% [27].

Merino in a meta-analysis related a lower infection rate in the case of malleable prosthesis compared to inflatable prosthesis (1.3% vs 3.5%) [28].

Menard in a study which examined over 400 patients with penile prosthesis after radical prostatectomy showed that the rate of complications for infection, revision or mechanical failure was less 5% and that the satisfaction rate was 86.1% [29]. The use of antibiotic impregnated penile prosthesis could significantly reduce the postoperative infection incidence and as well as the number of revision surgeries related to infectious complications. The overall postoperative complications are less than 5% and for infections is less than 2%. The incidence for mechanical failure is related of the follow-up period [30] and the overall incidence is around 5% [31]. Mechanical failure occurs more frequently in a case of multipiece inflatable prosthesis, due to their complexity. Malleable prosthesis due to the simple design are associated with a lower risk of mechanical problems. Lotan et al. related that the rate of survival (without technical problems) for malleable prosthesis compared to the inflatable ones is 87% vs 50% [32]. Paranhos encountered during his study a rate of mechanical problems in 3.59% of cases [21].

Atienza, in a meta-analysis regarding this problem found that the overall rate of mechanical failure was 1.4% [33]. He also found a rate of prosthesis exchange or withdrawal of 7.1%, which was similar to the rate that Paranhos described in his study of 8,68% [21].The causes of exchange or withdrawal were inadequate cylinder size, fracture of bioprosthesis (very rare, Parahos [21] reported 2 cases of patients with prosthesis fracture that didn’t know of their problem and they had a normal sexual activity, this issue was found during check-ups).

Yoon Seeob Ji [20] related that 21.6% of patients (16 patients) experienced mechanical problems and 5.4% (4 patients) mechanical problems. The mean follow-up period was 98 months. The mechanical problems encountered were caused by cylinder leakage 8.1% (6 patients), reservoir leakage 1.4% (1 patient out of 16) and pump failure 1.4%. In the case of the other 8 patients with mechanical failure the cause was not found because they didn’t undergo reoperation. The nonmechanical failure was due to erosion, infection of the prosthesis and other medical problems. All the patients with non mechanical failure underwent implant removal and surgical exploration. The survival rate of the inflatable prosthesis during the follow-ups over 5.10 and 15 years were 67.6%, 43.2% and 23%.

RESULTS

Compared with the conservative treatment for ED, the satisfaction rates achieved after penile prosthesis implantation are higher. According to the studies that we have analyzed, the overall patients satisfaction is 70-90%. The difference between pacient and their partners satisfaction rate is negligible, this difference ranging between 2 to 8%. The satisfaction rate regarding the adequate erection for sexual intercourse is 80-90%. The overall satisfaction rates for the malleable prostheses are lower compared with inflatable devices, 30-75%, respectively 75-90% for the inflatable prosthesis. The mechanical and overall survival rates for the malleable prosthesis range between 65-80% at 10 years, and 58-75% for the inflatable devices. Overall ease of use is rated as 78%.

Complications after implantation can be encountered in less than 5% of cases and infections in less than 2%. The likelihood of continued use is higher in the group of the patients with the inflatable prosthesis compared with the malleable ones 70-80%, respectively 50-60%. Up to 85-90% of patients with inflatable prosthesis would recommend them.

CONCLUSIONS

PPI is a high effective treatment for erectile dysfunction, refractory to pharmacological treatment. The technological improvements have decreased the rate of complications and revision surgeries which may appear after implantation, making these devices a safe solution and with great results for the men who choose penile prosthesis implantation as an answer to their problem. Many studies have related that the satisfaction rate after the operation was high, both for the patients and their partners [20]. The patients unsatisfaction after the implantation, was related to the unnatural feel of the sexual relations, due to the delayed ejaculation which was encountered in few cases and also because of the partners dissatisfaction, situation that may be related to the fact that the expectations were higher than the results. Thus before the operation, the doctor should make sure that the patient and his partners will have expectations in line with reality. Today, the three piece inflatable prosthesis is the most preferred one. Regarding the long term survival and complications of the penile prosthesis, the malleable prosthesis have a lower rate of mechanical problems than the inflatable ones, due to their less complex technological design, but patients satisfaction is higher in the group of inflatable prosthesis because they permit flaccidity and they have a better functional result. Patients who undergo implantation for the first time have a lower risk of postoperative complications compared with the patients who have had several interventions for different complications related to the penile prosthesis implant. The likelihood of continued use is higher in the group of the patients with the inflatable prosthesis compared with the malleable ones. The success of the implantation is very important, because the surgical revision is associated with a worse prognosis and a higher rate of complications. Regarding diabetes, several studies have shown a small correlation between diabetes mellitus and postoperatory infections [34,35]. Diabetes mellitus and radical prostatectomy are associated with a higher of postoperative complications. PPI enhances sexual capacity and self-confidence, therefore it should be considered as a final choice for patients with ED refractory to drugs.

TOT versus TVT – mesh surgical treatment in stress urinary incontinence

Ovidiu Bratu[1,2], D. Marcu[1], D. Spînu[1], A. Rădulescu[1], I. Oprea[1], Dan Mischianu[1,2]

Abstract: *Introduction: Stress urinary incontinence is a highly debilitating condition, with an important impact over the quality of life. When the conservative treatment fails, the surgical treatment is a viable solution. Minimally invasive sling procedures have become the gold standard of surgical management for stress urinary incontinence (SUI) in women.*

Material and methods: The study was conducted on 68 patients with stress urinary incontinence, 52 have undergone the retropubic tension-free vaginal tape and 16 patients were operated using the transobturator tape procedure. All the patients were evaluated before the operation and the indication of the surgical treatment was established on the basis of physical examination (all the patients had positive cough test), abdominal ultrasound (to determine postvoid residual urine volume), urinalysis and urine culture (the majority of the patients have had before the operation recurrent urinary tract infections).

Results: The satisfaction was similar in both groups of patients, with an average satisfaction rate of 91% for TVT and 86% for the patients who have undergone TOT procedure. The patients were in a proportion of 78,9% at menopause, with an average number of natural births of 1.9 and a mean BMI of 28.2. Regarding the surgical duration, this has varied between 20 and 40 minutes, being higher in the TVT cases (up to 5-7 minutes longer than TOT), because cystoscopy was performed during the operation to verify if the bladder was perforated or not. The urethral catheter was removed immediately after the operation in the case of the TOT procedure and in the day after the operation for the patients who have undergone TVT procedures (all of these patients associated genital prolapse). The hospitalization time was 3 days. We haven't encountered significant intraoperative and postoperative complications.

Conclusions: The TOT and TVT procedures have proven to be highly effective and safe methods in the treatment of SUI. There are no significant differences regarding the efficacy of these two surgical methods, but the risk of intraoperative complications is a little higher for the TVT procedure. The mid urethral sling procedures improve significantly the quality of life for patients with stress urinary incontinence.

INTRODUCTION

Female stress urinary incontinence is a major public health problem, with psychological and social effects and with an important impact over the quality of life. Stress urinary incontinence is defined as involuntary leakage of urine through the urethra during physical activities which increase the intra-abdominal

pressure, like laughter, coughing and sneezing, climbing stairs. There are numerous factors which contribute to the appearance of SUI: muscle weakness of pelvic diaphragm secondary to vaginal births, gynecological interventions, overweight and obesity, hormonal disorders. When the conservative treatment (bladder control exercises and pelvic floor muscle training, lifestyle modifications such as dietary habits, weight loss and physical activities) fails, the surgical treatment is a viable solution for SUI.

The first surgical treatment for stress urinary incontinence was described by Burch in the early 1960s and for almost 30 years, till the mid 1990s, it has remained the standard treatment for stress urinary incontinence. The long term follow-ups have suggested that this type of surgical treatment is effective, with a satisfaction rate at 5 years after the operation of nearly 80% and at 10 years of 70%. At the beginning of the 1990s, DeLancey established that the physiopathology of the SUI is associated with a defect at level of the bladder neck and urethra, related with the laxity of the surrounding tissue and as well as with the insufficiency of the urethral sphincter. He reported that the urethra lays on a layer of the endopelvic fascia and anterior vaginal wall and it is stabilized to the lateral by attachements of the levator ani muscle and arcus tendinous fascia. The urethral closure is conditioned by the urethral compression against the support offered by the anterior vaginal wall and the pubocervical fascia. This was the beginning of a new era in the treatment of SUI, the minimal surgical invasive treatment which would prove to be very effective.

In 1995, Ulmsten and Petros described the minimal invasive technique of retropubic tension-free vaginal tape. It was the first generation of sling operations, which used a polypropylene mesh. This procedure involves the blind penetration of the paraurethral and the retropubic space with a needle and the operator must exit with the needle behind the pubic symphysis. Because of its good results and low complication rate, it has become the solution for SUI. It is cited in the specialty literature that the rate of success ranges from 80 to 95%, after more than 5 years after the operation. Although the effective rate was high, it exist the intraoperative risk of complications such as bladder and bowel perforation and vascular injuries. As a solution to these concerns, Delorme described in 2001 another minimal invasive technique, the transobturator tape procedure. As well as the TVT the TOT is also a blind procedure. During the TOT surgery the puncture is performed at the clitoral level of the inferior ramus of the pubic bone and the operator must pass with the needle through the obturator foramen. This is the second generation of sling operations for SUI. It has been proven that the efficacy of the TOT procedure is similar to the TVT and with this type of procedure the risks of perforating the bladder or the bowels have disappeared, but more patients have groin pain postoperatively and vaginal or urethral erosion due to the polypropyline mesh. Both procedures are in current use for the SUI treatment, but because of its lower complication risks and similar efficacy, the TOT procedure is more popular.

MATERIALS AND METHODS

The purpose of this paper is to present our experience at the Urology Clinic of the Central Military Emergency University Hospital “Dr. Carol Davila” regarding the minimally invasive surgical treatment of stress urinary incontinence, using the vaginal sling procedures of TVT and TOT. We have analyzed several variables like: patient age, the number of vaginal births, body mass index, and gynecological interventions like hysterectomy. We present our cases and experience regarding perioperative complications and their management and as well as the efficacy rates, compared with other studies.

Between March 2010 and November 2015, in the Urology Clinic of the Central Military Emergency University Hospital “Dr. Carol Davila”, a number of 68 patients with stress urinary incontinence have been operated, using the minimally invasive technique of retropubic tension-free vaginal tape or the transobturator tape procedure. Out of the 68 patients who were admitted in our clinic for the surgical treatment of SUI, a number of 52 patients have undergone the transobturator tape procedure and only 16 patients were operated using the tension free vaginal tape technique. The TVT procedure was used only in the cases of the patients who associated genital prolapse. TVT has the same assembly principle as the TOT, but the incisions are made in the suprapubic region. The intraoperative complication risks, like bladder or bowel perforation, are higher in the case of the TVT compared with TOT. Therefore cystoscopy is essential after puncture. In all the cases with TVT we have performed cystoscopy to exclude a potential bladder perforation. Before the operation, all the patients were examined and the indication of the surgical treatment was established on the basis of physical examination (all the patients had positive cough test), abdominal ultrasound (to determine postvoid residual urine volume), urodynamic studies (testing was not performed in all the cases), urinalysis and urine culture (the majority of the patients have had before the operation recurrent urinary tract infections).

RESULTS

The mean age of the patients was 60.9 years. The patients were in a proportion of 78.9% at menopause and the average number of natural births was 1.9 ranging between zero and five. Mean BMI was 28.2, ranging from 23.3 to 37.4. Regarding the surgical duration this has varied between 20 and 40 minutes, being higher in TVT cases (up to 5-7 minutes longer than TOT), because cystoscopy was performed during the operation to verify if the bladder was perforated or not. The mean operative time was 27 minutes. Both surgeries required a 3 day hospitalization, the patients being discharged in all the cases the day following the surgery. The urethral catheter was removed immediately after the operation in the case of the TOT procedure and in the day following the operation for the patients who have undergone TVT procedures (all of these patients associated genital prolapse). In what concerns the urinary residual volume in the first days after the operation, we haven't noticed significant differences between the two types of procedures (the patients didn't accuse incomplete bladder voiding). All the patients were reevaluated at one month after the operation using the cough test, abdominal ultrasonography to determine the postvoid residual urine volume and to find potential complications secondary to the procedure. The long-term treatment outcomes were evaluated after 3, 6 and 12 months. Regarding the patients satisfaction, it was considered after the evaluation that the SUI was cured if the patient was completely continent, improved if partial urinary incontinence remained after the surgery and failed if the urinary incontinence remained the same or got worse after the surgery. The patient satisfaction was similar in both groups of patients, with an average satisfaction rate of 91% for TVT and 86% for patients who had undergone TOT procedure. Our results are in line with data from specialty literature.

J. Y. Han et all in a study about the effectiveness of TVT and TOT procedures in women with overactive bladder and stress urinary incontinence, stated that TVT and TOT procedures have decreased the proportion of the daily incontinence in these patients, with a slightly higher efficacy in the TVT group. In a study published in 2013 the ”Scandinavian Journal of Urology”, V. Nyyssonen concluded that 70% of the patients that were included in the study, with symptoms of detrusor over activity, declared significant improvement after the mid urethral tape surgery. There was no significant difference between the two operating techniques.

Cerniauskiene and collaborators in a comparative study regarding TOT and TVT outcomes reported that the satisfaction rate for the patients who have undergone the TOT procedure was 81,3%, meanwhile the satisfaction rate for the TVT group was 90%.

Zyckowsci et al stated in their comparative study regarding the TVT and TOT surgery, that the patient satisfaction rate at 6 months after surgery was 96,4% for TVT patients and 96.1% for TOT patients. Regarding the cough test and pad test, they have stated that it was negative in 91.5% and 94.4% in TVT cases, and in 93% and 93% TOT cases. The findings in our study were similar to general literature. We have observed in our study that the cough test was negative for 91.2% of TVT cases and 92% of TOT cases at 6 months, and the pad test was negative for 94% of TVT cases and 92.8% of TOT cases at 6 months postoperative. We haven't encountered significant intraoperative and postoperative complications. We haven't had significant bleeding during the interventions. The mean blood loss was under 25 ml. Local hematoma was encountered in 5 TOT cases and in only one TVT case and conservative treatment was effective. We haven't had any bladder or bowel perforation complications. We have encountered one case of relapse of incontinence due to the exaggerated physical activities, at two and a half years after the operation. In this case, we have performed a second intervention. We have removed the mid urethral portion of the tape and we have performed the tension-free vaginal tape procedure. The results at 3 and 6 months after the operation were good, although it is mentioned in general literature that in the case of reintervention for relapse of SUI the outcomes may not be as good as in the case of the first operation.

De novo overactive bladder symptoms ranged between 3 and 4.5% without differences between TOT and TVT patients. The pharmacological treatment which was applied in these cases has had good results. There are studies in which it is mentioned that the incidence of the overactive bladder symptoms ranges between 4 and 30 % after the operation.

Bladder botulinum toxin A injection and percutaneous sacral nerve modulation have proven to be good alternatives for the TOT and TVT surgery. Since its introduction (2005-2006) the number of patients who were admitted for bladder botulinum toxin A injections has increased constantly, overtaking in 2010 the number of TVT/TOT procedures. So far we haven't applied this method of treatment for the SUI.

With the passing of the time, the number of patients who have undergone TOT/TVT surgery and have chosen to remove their tapes grows. Most tape removals are performed at a relatively short time after the procedure, the main cause being urinary retention or tape extrusion. We haven't encountered such situations in our study.

CONCLUSIONS

The minimally invasive surgical treatment of SUI (TOT/TVT) has become the gold standard for patients with this debilitating condition. Mid-urethral sling surgery is performed to fix the urethra and involves few anatomic changings in the surrounding tissues.

These procedures have proven to be highly effective, increasing the quality of life for the patients who suffer from SUI. Regarding the efficacy rate of this two type of procedures it hasn't been noticed significant differences in the study that we have done, our results being in line with specialty data.

In terms of complications the risks are higher for the TVT procedure, due to the risk of bowel or bladder perforation. To exclude this possible accident, which may happen during TVT, cystoscopy is essential. Therefore, the TOT procedure has become more popular.

Till the introduction of TVT and TOT, SUI was either simply accepted or required invasive surgery.

Penile fracture – clinical case presentation

C. Farcaș[1], V. Botea[1], R. Popescu[1], Marius Dinu[1], Ovidiu Bratu[1,2], D. Spînu[1], Dan Mischianu[1,2]

INTRODUCTION

Fracture of the penis is a rupture of the tunica albuginea of the corpus cavernosum, usually while the penis is rigid and erect. When erect, the albuginea layer stretches so far until its thickness reaches approximately 0.25 – 0.5 mm, compared with a 2 mm thick when flaccid. Thus the erect penis is much more vulnerable to serious damage from blunt trauma than the pendulous, flaccid penis. The most common cause of penile fracture is vigorous vaginal intercourse, more likely when woman is on top, but it can also occur during masturbation, forced bending of the erect penis or any mechanical trauma to the erect penis. The classic presentation described by the patient cracking or popping sound, followed by rapid detumescence, severe pain, ecchymosis of the penile skin, and swelling of the affected side with deviation of the penis shaft away from the affected side. In most cases, the penile fracture is a transverse corporeal tear close to the corpus spongiosum on the ventral aspect of penis shaft or on the lateral aspect and the tunical tear is usually 1 to 2 cm in length. The rupture can involve one or both corpora cavernosa as well as corpus spongiosum with the contained urethra therefore urethral rupture can also occur in. Most urethral injuries are associated with gross hematuria, blood at the meatus or inability to void, although the absence of these findings does not definitively rule aut urethral injury.

DIAGNOSIS AND IMAGING

The penile fracture is considered by the most to be a clinical diagnosis, with little need for imaging if the patient presents with a convincing history and physical examination. However given that urethral injury occurs not infrequently, preoperative exploration of the urethra should be considered when urethral injury is suspected (urethrography or flexible/rigid cystoscopy). There are numerous reports of the accuracy of cavernosography and magnetic resonance imaging (MRI), inspite of their accurate results, they are sometimes too invasive, time consuming or costly to justify, particularly when the diagnosis can be established by clinical examination. Ultrasonography although noninvasive and easy to perform is also associated with significant false-negative studies. Another condition that may mimic penile fracture is rupture of the dorsal penile artery or vein during sexual intercourse, in these circumstances physical examination may not be adequate for definitive diagnosis of a corporeal tear and further investigations should be performed like MRI, ultrasonography or even surgical exploration.

MANAGEMENT OF PENILE FRACTURE

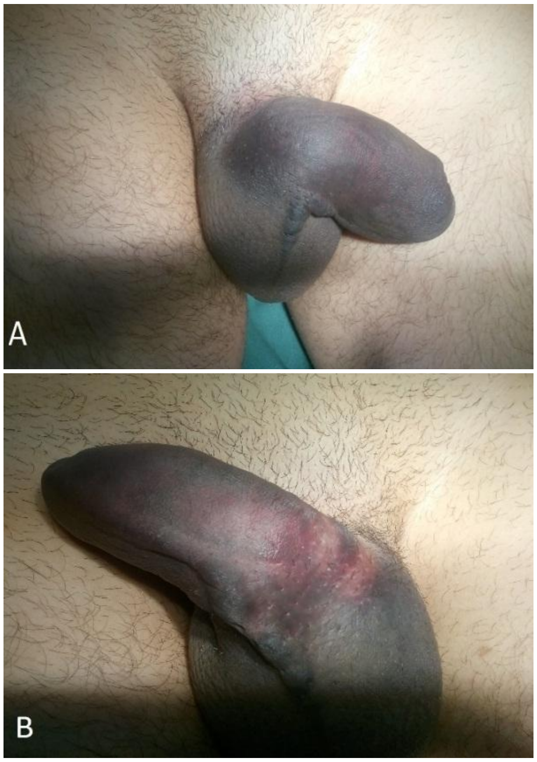
Multiple publications indicate that suspected penile fractures should be promptly investigated and surgically repaired. Many reports show low complication rate and good outcomes as a result of immediate surgical repair, (less than 5% penile curvature after immediate surgical repair – El Atat et al, 2008) as the favorite approach for treatment of this urological emergency. Conservative management can also be an option in patients with uncomplicated albugineal tears, without extensive hematoma or urethral injury, but most untreated fractures usually develop delayed and persistent penile pain or curvature with erection. Conservative management of penile fracture has been associated with penile curvature in more than 10% of patients, abscess or debilitating plaques in 25% to 30%, and significantly longer hospitalization times and recovery (Meares,1971; Nicolaisen et al, 1983; Kalash and Young, 1984; Orvis and McAninch, 1989).

Although small lateral incisions may be used for localized hematomas or palpable tunical defects, a distal circumcising incision is the best option in most cases thus providing exposure to all three penile compartments. For the closing of the tunical defect is recommended to use interrupted absorbable suture 2-0 or 3-0. Deep corporeal vascular ligation or extensive debridement of the underlying erectile delicate tissue should be avoided. Timing of the intervention may also influence the long-term outcome of erectile function or postoperative complications in the way that the patient undergoing surgical repair intervention in the first 8 h after injury has significantly better long-term results than those having surgery delayed 24-36 h after fracture occurrence (Asgari et al, 1996; Karadeniz et al, 1996).

PATIENT, METHOD AND RESULTS

A 31 years old patient presents in the emergency department in our hospital at approximately 03:15 a.m., this being the third medical unit he was attending that day, accusing pain in the external genital area associated with extended hematoma of the penis and scrotum with the deviation of the penis on the left side (Figure 1A). Further anamnesis discovers posttraumatic injury of the penis while sexual intercourse that happened at approximately 01:00 a.m. The patient describes powerful bending of the penile shaft, and at the same time strong local pain, accompanied by a snapping sound and after that immediate detumescence of the penis with decrease in pain intensity. Patient describes urine voiding normal and no bleeding out of the urethra.

Figure 1. Extended hematoma of the penis and scrotum and pathological deviation of the penis shaft on the left side (A)



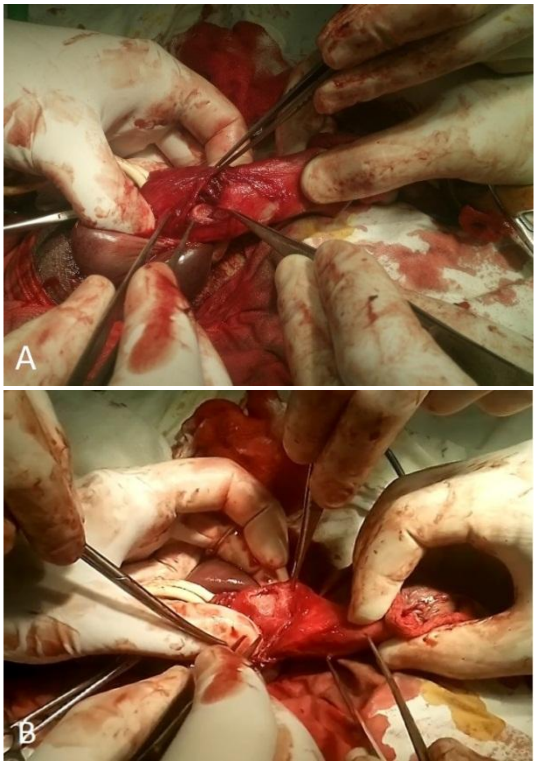
The patient is admitted in our department and undergoes a soft tissue ultrasound that reveals a local hematoma of the penis and a small breach of approximately 3-4 mm in diameter which is situated on the ventral aspect of the right cavernous body, of the proximal third of penis shaft.

Emergency surgery is decided, with spinal anesthesia at 08:00 in the morning (7 hours after the injury occurrence).

After local antiseptic measures, a 14 Fr. Foley catheter was placed before the beginning of the intervention. A distal circumcising incision is made at approximately one cm proximal of the coronal sulcus, followed by degloving the penis, and exposing the tunical fracture site in the albuginea.

The tunical tear was fond on the ventral aspect of the corpora cavernosum at a distance of 3-4 cm from the base of the penis.

Figure 2. A: albugineal tear on the left cavernous body. B: albugineal tear on the right cavernous body.



The rupture site was much greater than the one observed on the ultrasound scan. The real size of the tear was about 3 cm and involved both cavernous body on their anterior aspect, as well as the septum of the albuginea underneath the spongy body (Figure 2, A and B).

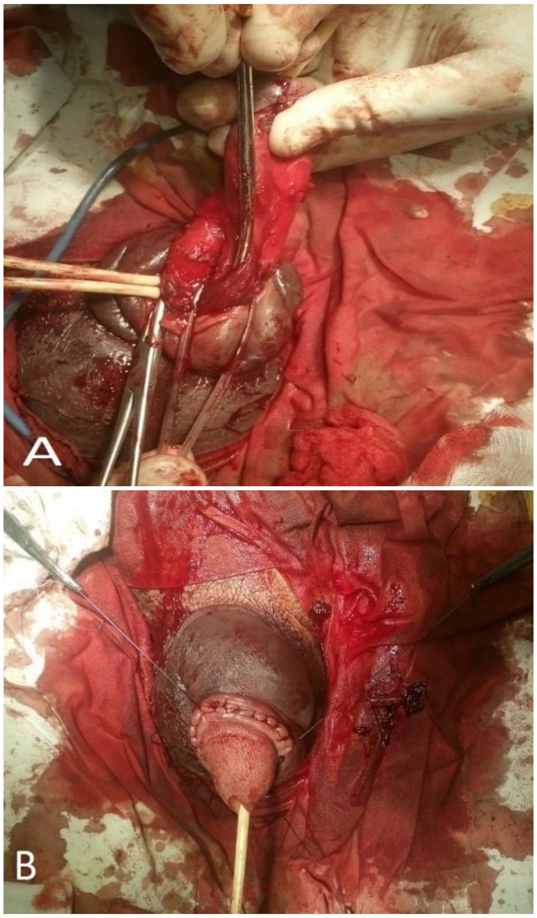
The spongy body was carefully dissected from the corpora cavernosa and so the entire length of the transversal rupture was individualized.

A temporary elastic Tourniquet at the base of the penis was necessary for local control of bleeding.

Defect repair was performed with separate absorbable 3-0 USP sutures. For the full length of the breach 14 to 15 separate sutures were needed. Final aspect of the repaired defect of the tunica albuginea can be seen in both pictures below (Figure 3, A-B).

The patient's evolution was favorable under antibiotic therapy for 5 days with no infectious complications. Second day postop he mentioned a mild morning erection although he was under treatment with Cyproterone acetate 50 mg twice a day and Diazepamum 10 mg a day in two doses.

Figure 3. A: ventral aspect of penis with the spongy body mounted on a lasso and the albugineal surure. B: final aspect after suture of the skin.



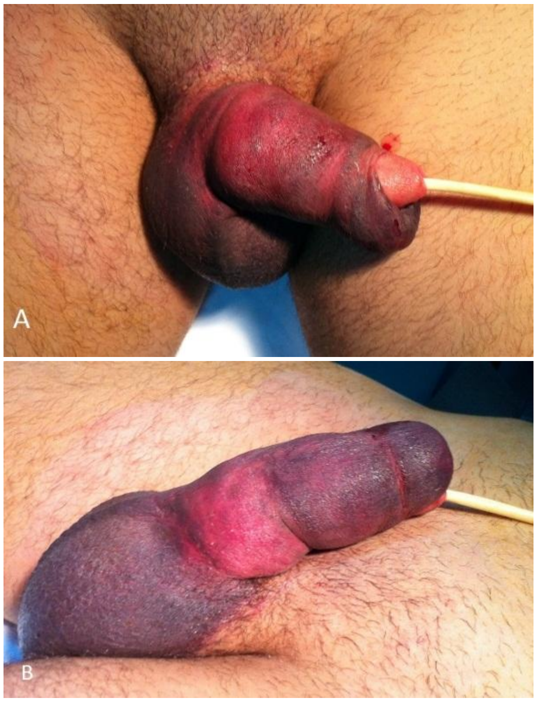
DISCUSSION AND CONCLUSION

Penile fracture is a rare case of urological emergency that should undergo in most of cases emergency surgical treatment.

The immediate surgical repair attitude (<8 h) is the preferred approach for treatment of penile fracture as reported in numerous centers around the world due to their low complication rates.

While the conservative approach is described in patients with small and uncomplicated tears, most unrepaired fractures develop late penile curvature or pain with erection.

Figure 4. Aspect of the penis and scrotum the second day postoperatively while patient still carries a Foley catheter.



The urgency of surgical exploration justified in our case the discrepancy between imaging findings and the reality found during the surgical exploration.

Albugineal tear that involves the both corpora cavernosum is extremely rare and also usually is associated with urethral injury, which in this patient, the last one, was not the case.

The incidence of concomitant urethral injury is approximately 20 % in Europe and the USA. Most urethral injuries are associated with urethral bleeding or gross hematuria or even inability to void, but also, the absence of these signs does not exclude a potential urethral injury.

Guidelines for authors

Thank you for your interest in *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully prior to submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission in accordance with the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

We look forward to your submission.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians and Pharmacists. The Journal publishes peer-reviewed original papers, reviews, metaanalyses and systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor will not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer reviewed under the direction of an Editor. The Editor reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

(1) accessible to the public at no charge;

(2) searchable by standard, electronic (Internet-based) methods;

(3) open to all prospective registrants free of charge or at minimal cost;

(4) validates registered information;

(5) identifies trials with a unique number; and

(6) includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of last follow-up, target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, with the exception of Editorials, must contain an abstract of no more than 250 words. Abstracts for original articles should be formatted into subheadings, as detailed below. Titles must not be longer than 120 characters (including spaces).

Editorials

These are invited by the Editor-in-Chief or their delegated editor, and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure and cite up to 15 references, including the source article [this should be cited as Military Med. Today (year); (vol): [this issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine, and advances in clinical practice. Most published reviews are in response to editorial invitation, including thematically related "mini-series" of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are limited to 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews have a word limit of 3500–5000 words, with an abstract of up to 250 words and up to 75 references and 3–7 figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical and/or historical aspects of the subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with a clear relevance to disease mechanisms and new therapies. Original articles are limited to 3000 words, with an abstract of up to 250 words and up to 50 references and 3–7 figures and tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Education and Imaging Coordinating Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to diagnosis or which are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, presentation of analogous cases or related images from a similar case might be appropriate. Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background to and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication', as presented at http://www.ICMJE.org/.

Spelling. The journal uses US spelling and authors should therefore follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units. All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations should be used sparingly and only where they ease the reader's task by reducing repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: title page; main text file; figures.

Title page

The title page should contain (i) a short informative title that contains the major key words. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgements. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors'

industrial links and affiliations. In the case of clinical trials or any article describing use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented in the following order: (i) abstract and key words, (ii) text, (iii) references, (iv) tables (each table complete with title and footnotes), (vii) figure legends. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 250 words or less the purpose, basic procedures, main findings and principal conclusions of the study. Divide the abstract with the headings: *Background and Aim, Methods, Results, Conclusions*. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to five keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser—(http://www.nlm.nih.gov/mesh/meshhome.html).

Text

Authors should use subheadings to divide the sections of their manuscript: *Introduction, Methods, Results, Discussion, Acknowledgments and References*.

References

The Vancouver system of referencing should be used. In the text, references should be cited using superscript Arabic numerals in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or less; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

References should be listed in the following form:

Number references in the order cited as Arabic numerals in parentheses on the line. Only literature that is published or in press (with the name of the publication known) may be numbered and listed; abstracts and letters to the editor may be cited, but they must be less than 3 years old and identified as such. Refer to only in the text, in parentheses, other material (manuscripts submitted, unpublished data, personal communications, and the like) as in the following example: (Chercheur X, unpublished data). If the owner of the unpublished data or personal communication is not an author of the manuscript under review, a signed statement is required verifying the accuracy of the attributed information and agreement to its publication. Use Index Medicus as the style guide for references and other journal abbreviations. List all authors up to six, using six and "et al." when the number is greater than six.

Tables

Tables should be self-contained and complement, but not duplicate, information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table, legend and footnotes must be understandable without reference to the text. Vertical lines should not be used to separate columns. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, §, ¶ should be used (in that order) and *, **, *** should be reserved for *P*-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication: Although low quality images are adequate for review purposes, publication requires high quality images to prevent the final product being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at daniel_costache@yahoo.com

A cover letter containing an authorship statement should be included.

The cover letter should include a statement covering each of the following areas:

1. Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author.
2. Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.
3. A statement outlining how ethical clearance has been obtained for the research, particularly in relation to studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research

must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

4. For research involving pharmacological agents, devices or medical technology, a clear Conflict of Interest statement in relation to any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

5. For clinical trials, that these have been registered in a publically accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review.

Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word-files need to be included upon submission: A title page file and a main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using Microsoft Word, doubled-spaced. The top, bottom and side margins should be 30 mm. All pages should be numbered consecutively in the top right-hand corner, beginning with the first page of the main text file.

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, low-resolution figures saved as .jpg or .bmp files should be uploaded, for ease of transmission during the review process. Upon acceptance of the article, high-resolution figures (at least 300 d.p.i.) saved as .eps or .tif files will be required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted papers will be passed to production team for publication. The author identified as the formal corresponding author for the paper will receive an email, being asked to complete an electronic license agreement on behalf of all authors on the paper.

Accepted Articles

The accepted ‘in press’ manuscripts are published online very soon after acceptance, prior to copy-editing or typesetting. Accepted Articles are published online a few days after final acceptance, appear in PDF format only, are given a Digital Object Identifier (DOI), which allows them to be cited and tracked. After print publication, the DOI remains valid and can continue to be used to cite and access the article. Given that copyright licensing is a condition of publication, a completed copyright form is required before a manuscript can be processed as an Accepted Article.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing instructions on how to provide proof corrections to the article. It is therefore essential that a working e-mail address is provided for the corresponding author. Proofs should be corrected carefully; the responsibility for detecting errors lies with the author. The proof should be checked, and approval to publish the article should be emailed to the Publisher by the date indicated; otherwise, it may be signed off on by the Editor or held over to the next issue.

Offprint

A PDF reprint of the article will be supplied free of charge to the corresponding author. Additional printed offprint may be ordered for a fee.

COPYRIGHT, LICENSING AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is accepted.

Climbing – between athletic performance and psychological performance

Antonia I. Vasile[1], Florin Pelin[1], Monica I. Stănescu[1]

Abstract: *The aim of this research is to investigate different aspects of the functioning of the psychological system of performance climbers in Romania. We look for correlations between the concepts of competitive anxiety, self-esteem, motivation, willingness to take sports risks and age, sport experience and competitive experience, performance level. We also try to find out if the first contacts with the climbing world resulted in a favouring of the environment in which the athlete chooses his/her performance goals. Specifically, we aim to divide climbers into two categories, those with a passion for panel climbing (indoor) and those with a passion for rock climbing (outdoor). We did not distinguish between the bouldering challenge and the difficult challenge. In addition, we want to analyse the level of competitive anxiety of athletes in national climbing in order to objectify again the idea that the coach and sport psychologist must be able to identify, in the crucial moments before and during the competition, which athletes need motivation, which ones are anxious, which ones feel good and which ones can be left alone. We can classify athletes who need relaxation, activation or mindfulness sessions.*

Objectives: • Identifying the performance level of Romanian climbing athletes at the moment; • Highlighting the motivational dimensions of performance climbers in relation to the practice of the sport; • Investigating the passion for indoor versus outdoor climbing, with implications on the level of intrinsic and extrinsic motivation and self-esteem; • Knowing the level of competitive anxiety, with a focus on the fine delineation between being debilitating or facilitating for athletes.

Methodology: The research method used was the application of instruments (psychological tests and an opinion questionnaire). The test was administered between January-March 2020, online via google docs, on 28 performance climbers, aged between 13 and 48 years, female and male, juniors and seniors.

Results: The climber's personality shines through on the rock (outdoors), where the desirability, and if it exists, is not a social one, but is a genuine desire to push your own limits, to face difficult challenges, to feel danger, to develop your wits and to know where to stop. These concepts correspond entirely to intrinsic motivation and a more mature personality, both in social and sporting terms, from this maturity a fundamental dimension of which is the match between real possibilities and aspirations.

Conclusion: Rock climbing involves bringing out the authentic self when you are with yourself, compared to a sports competition held at the panel that highlights a socially constructed self, adapted to the fans, an image and smiles to support your image in the sporting world. In other words, avid rock athletes will train at the panel with low anxiety looking at these workouts only as technical drills for the future challenges they will face at the cliff. They are less reliant on extrinsic motivation when conducting their training on the panel, keeping it somewhere in the background for what they consider their own goals. For those for whom the stakes are to increase the difficulty of their rock routes, those will be the situations where they will have higher anxiety and a higher need to rely on extrinsic motivation as well until they reach the maturity where performance is staked by intrinsic determination.

Keywords: *indoor climbing, outdoor climbing, competitive anxiety, performance, motivation, sport experience*

INTRODUCTION

Performance can be defined as the outcome of an individual as a result of performing a task that can be measured and evaluated by an observer or by him/her (the referee or him/her as an athlete). This evaluation in climbing is quantitative – number of routes completed, number of holds achieved,

Corresponding author: Antonia Ioana Vasile
antoniaioana97.vasile@gmail.com

[1] The National University of Physical Education and Sports, 140 Constantin Noica Str., 060057 Bucharest, Romania

time taken to complete the route.

Sporting performance is the athlete's bio-psycho-social value, expressed in the context of official competitions, which is assessed according to rigorously established scales and is due to a multiply determined capacity (the sum of all abilities).

Sports performance is the result of factors that depend on the athlete's personality, attitudinal orientation and motivation to perform. The limit activity is at the choice of the athlete who wants to reach a stage of excellence, break a personal or world record, win a major competition. Maximising performance can only be achieved after maximising the athlete's personality. Unfortunately, many sports trainers see the athlete as a biological machine programmed to perform certain motor actions in a repetitive number, placing little emphasis on what athletes think and feel.

It all starts with the genetic make-up of each athlete. Any subject can be distinguished: biological traits (arm span, height, weight etc – there is no typical top climber (there are very tall champions like Adam Ondra, but also short ones like Juliane Wurm – each has advantages and disadvantages for the movements in the trails that he/she has to know how to use and be aware of), physiological traits (heart rate, respiratory capacity etc), psychological traits (the mental state of the athlete) and metabolic traits (aerobic, anaerobic processes, lactic acid capacity etc) [1,2].

There are four types of trainings to be developed:

1) Physical training – there are two types: general and specific physical training. The specific one involves exercises on specialised training boards (pulls on slipped holds, on spiked holds, for example), specific exercises for body-tension (a muscle tension that cumulates several muscle groups at the same time). What is specific to climbing is working against gravity and working with your own body weight.

2) Technical training which involves three components: Initially, specific training – this refers to learning general training rules (such as to perform a route you need to double the last top hold or for the starting position you need to have all four limbs in certain holds); learning to fall on the mat for the bouldering event (teaching the athlete to jump on the mat by bending the knees, for example, to avoid injury); learning how to belay for the climbing event (type of cuff, type of rope-head, use of the spinning device, tying the safety knot); basic technical training – learning, reinforcing and perfecting technical procedures, followed by their application on routes of increased difficulty; specialised kinaesthetic system – developing techniques for holding various holds

3) Tactical training – tactical training is not similar to that in combat or opponent sports. We discuss the athletes' pattern of approaching routes and what strategies they can use to achieve a complete ascent: Route visualization – a correct and efficient visualization of the route the athlete has to achieve will save him/her many attempts: route approach strategy (e.g. the three attempts method), creative imaginationthe idea that routes differ from competition to competition (except for the speed event) is emphasized and therefore the athlete must allow his/her imagination to find variations and alternatives to achieve the route [3].

4) Psychological training which can be defined on three levels: basic psychological training – involves the formation of athletes' personality, character, specific attitudes and the skill to carry out sports activities systematically and organized. It also focuses on physical hygiene, social skills, nutrition and sleep hygiene, and the importance of invisible training; specific psychological training – aims to develop the physical, psychomotor and psychological skills needed for the sport branch. The importance of shaping the competition in training is stressed so that the athlete perceives the stakes and the tension created by the competition.

HYPOTHESES

1) There are significant differences between the group of rock enthusiasts and panel enthusiasts in terms of personality questionnaire scores and level of motivation.

2) There are significant differences between juniors and seniors in terms of motivation level.

3) There are significant differences between the group of first mountain experience and first panel experience in terms of anxiety and motivation.

4) There are significant differences in competitive anxiety by level of competitive experience and level of sport experience.

5) There is a statistically significant correlation between competitive experience and level of competitive anxiety.

6) There is a statistically significant correlation between the level of extrinsic motivation and the level of intrinsic motivation.

7) There is a statistically significant correlation between the level of self-esteem and the level of intrinsic motivation.

8) There is a statistically significant correlation between the

level of performance and the level of extrinsic motivation.

METHODOLOGY

The methodology of this study is based on the following steps:

- choice of the problem to be researched;
- determining the group of athletes to which we will apply the research instruments;
- developing the research questionnaire and its rating;
- entering the questionnaire in google docs;
- creating the database with the athletes' answers in google docs;
- analysing the database using descriptive and inferential statistics;
- analysing the confirmation or refutation of working hypotheses;
- making psychological assumptions and interpretations of the results based on statistical analysis and with reference to the literature;
- outlining the conclusions of the present research;
- highlighting possible directions for further research.

1. Participants

The study was carried out on 28 participants. We considered only performance climbers who regularly participate in internal and/or external competitions. The ages of the subjects ranged from 13 to 48 years. There are both female (11) and male (17) participants. The study group can be divided into seniors (19) and juniors, up to 20 years old (9), according to the type of competitions in which they can participate internationally (seniors are considered to be at least 20 years old, and the categories for juniors are 14-15 years old, 16-17 years old, 18-19 years old – but in senior competitions, competitors can participate from the age of 16). Criteria for inclusion in the study include: a training frequency of at least two training sessions per week and active participation in national and international competitions during 2018-2019 (competitors in National Climbing Championships, National Bouldering Championships, Boulder Games, World or European Cup stages). Athletes fall only in the Masters category (female or male) [4].

2. Tools

- Introductory questionnaire: to record participants' factual data (age, gender, sporting experience, competitive experience, maximum performance level);

- the Impulsive Sensation Seeking and Social Desirability scales of the Zuckerman – Kuhlman Personality Questionnaire, ZKPQ

The Impulsive Sensation Seeking scale contains two clusters of items, which measure two constructs: the Impulsivity construct (which refers to the lack of planning and the tendency to act quickly, on impulse, without prior reflection) and the Sensation Seeking construct (which describes the general need for excitement and agitation, the preference for unexpected situations and friends with unpredictable behaviour, and the need for change and novelty).

The Social Desirability Scale expresses the subject's need/ desire to present him/herself in a particular way, as he/she believes at that moment in time that the entourage expects of him/her. It expresses a kind of poikilotimia, moulding on the mood and expectations of the entourage, the unconscious aim being to be liked, accepted and to build and sustain a self-image slightly higher than the subject concerned knows he/she deserves;

- competitive anxiety questionnaire taken from the research literature (“Psihologia sportului. Ghid pentru optimizarea performanțelor”, Stephen Bull, pp. 64-67)

It is a questionnaire that measures competitive anxiety as a trait. The first part (with the answers Rarely/Sometimes/ Often) indicates how often symptoms occur before competition. The higher the score (values between 10 and 30), the more prone the athlete is to competitive anxiety. The second part involves measuring the score that represents how facilitating or debilitating the anxiety is for the athlete. It attempts to separate positive (facilitating, enabling, constructive) and negative (debilitating, anxiety-provoking, destructive) emotions;

- Rosenberg's self-esteem scale (1965)

This scale is used to measure the athlete's overall sense of self-worth and self-acceptance. It is a four-choice scale (1-4 items), scores range from 10-40. It divides subjects as having: low, medium and high self-esteem.

- Sport motivation scale taken from the research literature) [5], translated from English into Romanian, preserving the meaning of the items and adapting them for the Romanian sport culture.

This scale is divided into several concepts: intrinsic motivation, extrinsic motivation and amotivation. Intrinsic motivation refers to the desire to engage in an activity simply for the pleasure and satisfaction that comes from the action [6]. If a person is internally motivated, he or she will want to perform for the self, not staked by material rewards or external constraints [7]. Intrinsic motivation involves: intrinsic motivation to know, intrinsic motivation to achieve, and intrinsic motivation to have stimulating experiences.

Knowledge motivation involves curiosity, exploration, a wish to learn and a genuine wish to understand. It can be seen as driving the athlete to act for the pleasure and satisfaction of learning a new experience, of trying to understand something previously unheard of.

Achievement motivation is a concept that in psychology is also referred to as self-improvement motivation, efficacy motivation or goal orientation. It can be defined as engaging in an activity because of the pleasure and satisfaction you get from the attempt, from the idea of creating something. An example from sport might be: the attempt to perfect a difficult technique to gain personal satisfaction.

Motivation towards stimulating experiences refers to the athlete's wish to try an activity for the stimulating sensation it generates (example: sensory stimulation, aesthetic experience, amusement, pleasure).

Extrinsic motivation involves engaging in a behaviour that has a purpose, a purpose that is not for personal development [6]. Grolnick [8] in 1990 investigated extrinsic motivation beyond external conditioning and postulated three dimensions of extrinsic motivation: unconscious extrinsic motivation, identification extrinsic motivation and regulatory extrinsic motivation.

Regulatory motivation is the one most often found in the research literature. It explains why certain behaviours are driven by external sources, such as material rewards, money prizes, trophies, medals, diplomas or constraints imposed by others [7]. An example from sport psychology might be competitors expecting rewards from parents or coaches. In this case, sport is not practised for pleasure or wish, but for rewards or to avoid negative consequences (criticism, arguments, etc.).

Unconscious motivation involves an internalisation of external rewards and therefore they are no longer necessary. In contrast, positive sporting behaviour is reinforced by internal pressures such as anxiety or guilt. Such examples might be athletes who engage in physical activity because they do not feel good in their bodies, they do not feel they are in good physical shape.

Identifying motivation refers to the moment when the athlete becomes autonomous and is able to value and judge his/her own behaviour. It is still an external, material goal, but it is internally regulated and self-determined (e.g. to achieve their own goals).

Amotivation is found when the athlete can no longer specify the reason for practising sport, he/she does not know why he/she should continue or whether he/she should continue practising. Eventually, they may decide to withdraw from the activity;

- opinion questionnaire on rock climbing, a questionnaire specially developed for the purpose of this research, on the interest of Romanian high-performance athletes in rock climbing and the differentiation of climbers into the two categories – rock enthusiasts and panel enthusiasts.

3. Experimental model

Variables are: age, performance level, competitive experience, sport experience, level of competitive anxiety, level of self-esteem, intrinsic motivation, extrinsic motivation, impulsive sensation seeking scale, social desirability scale, passion. Independent variables are: age, passion, competitive experience, sport experience, personality scales (impulsive sensation seeking and social desirability). Dependent variables are: competitive anxiety, performance level, motivation scales, self-esteem.

4. Data collection procedure

The research method used was the application of instruments (psychological tests and an opinion questionnaire). The test was administered during January-March 2020, in an online environment, through google docs.

The tests applied are:

- ZKPQ test, of which we used only two scales (impulsive sensation seeking and social desirability) – 28 questions. The answers are True/False. The questionnaire is calibrated and validated on the Romanian population by Test Central (Cronbach's alpha coefficient of internal validity is explained in the test manual).

- Competitive anxiety test taken from the book „Psihologia sportului- Ghid pentru optimizarea performanțelor”/"Sport Psychology – A Guide to Optimising Performance", Stephen Bull, pages 64-67 – 15 questions. It has three response options (Rarely/Sometimes/Often) and a Likert scale from 1 to 7 (from very debilitating to very facilitating).

- Rosenberg Self-Esteem Scale – 10 questions. Items are scored with four response possibilities between strongly disagree (1 point) and strongly agree (4 points).

- Sport Motivation Scale (SMS) (taken from Journal of Sport & Exercise Psychology, volume 15, pages 35-53) – 28 questions, translated from English into Romanian, keeping the meaning of the items and adapting them for the Romanian sport culture. It is scored from 1 to 7 (1, 2 = does not correspond at all; 3, 4, 5 = corresponds moderately; 6, 7 = corresponds very much). The scoring is as follows: Amotivation corresponds to items 3, 5, 19, 28; extrinsic motivation consists of items 6, 10, 16, 22; intrinsic motivation has items 1, 2, 4, 8, 12, 13, 15, 18, 20, 23, 25, 27; identified motivation consists of items 7, 11, 17, 24; and unconscious motivation corresponds to the sum of items 9, 14, 21, 26.

A total of 104 questions were asked. Completion of the questionnaire takes approximately 8 minutes.

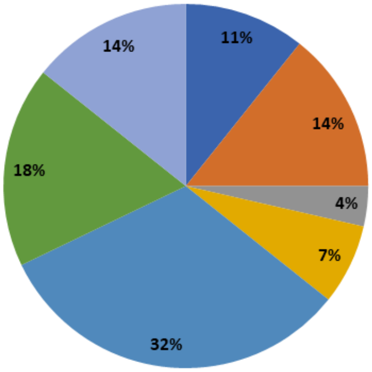
RESULTS

Data analysis and interpretation

The following figures illustrate classifications of athletes according to an independent variable.

The graph from Figure 1 shows the distribution of the sample according to performance level.

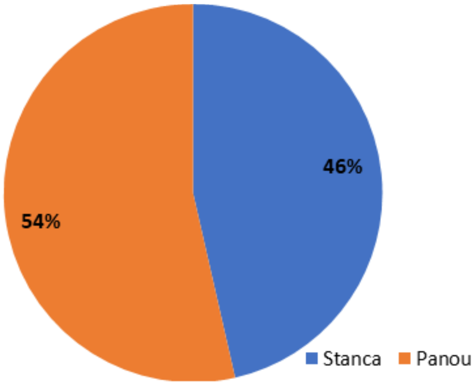
Figure 1: Performance level of Romanian climbers



(Performance level: Balkan champion, national champion, I participated in a final/semi-final in European competition, I participated in a Balkan final, national final, participation in a world competition, I never participated in a final)

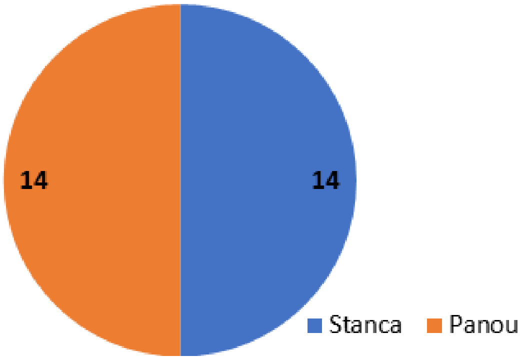
The graph from Figure 2 shows the distribution of the group according to the passion for rock or panel.

Figure 2: The passion of the athletes in the group



The graph from Figure 3 shows the group of athletes who had first contact with rock climbing versus those who had first contact with panel climbing.

Figure 3: First experience of athletes in the group



Following the achievement of the database after completing the questionnaire, 16 variables were identified: gender, age, sport experience (how many years of climbing), competitive experience (how long they have been participating in Masters competitions), performance level, impulsive sensation seeking score, social desirability score, self-esteem score, competitive anxiety score, competitive anxiety facilitation score, motivation scores (intrinsic, extrinsic, unconscious, identified motivation and amotivation), passion (rock or panel) and first experience (first contact with climbing was at panel or rock).

To decide the passion score, each question had a panel or rock response for which a score was given (panel=0, rock=1). Questions 1, 2, 4, 5, 6, 8, 10, 12, 13 (see Annex 1) were used to determine the passion scale score. Question 11 was used to determine the first experience. Of the 13 questions, 9 were with an exact response (rock or panel) to discover the athlete's passion, so the maximum possible score was 9. The remaining items were considered distracting and are not summed to determine the final score. Those scoring 0-4 were framed as having passion for the panel and those scoring 5-9 were framed as having passion for the rock.

In order to classify the level of performance, taking into account the general levels of Romanian climbers in relation to external competitions (championships or world cups), we ranked the athletes according to the following score: 1 point = Balkan champion, 2 points = national champion, 3 points = participated in a European final/semi-final, 4 points = participated in a Balkan final, 5 points = national final, 6 points = participated in a world competition, 7 points = participated in European competition, 8 points = participated in a Balkan competition, 9 points = never participated in a final

The lower the score, the higher the performance level of the athlete. Of course, it is a question about the highest level of performance perceived by him (for example, if an athlete is a national champion and has participated in European competition but came 44/49, he/she will not consider the highest level to be worth 7 points).

For the other scales, the score was calculated according to the scoring mode in the inventory.

Descriptive analysis

The descriptive statistics for the sample/group researched are illustrated in Table 1 and Table 2.

Table 1: Descriptive analysis

	Age	Exp-sport	Exp-comp	Sensation seeking	Desirability	Anxiety	Facilitation
Mean	27.07	12.02	8.64	11.04	1.82	20.96	30.04

Count	28.00	28.00	28.00	28.00	28.00	28.00

One of the objectives of the present work was to determine the anxiety dimension of the athletes in the chosen group, demonstrating the importance of knowing each athlete individually, so that the coach can figure out if the athlete needs activation, relaxation, mindfulness or to be left alone [9]. There were two dimensions investigated: the level of competitive anxiety and the anxiety facilitation dimension which was intended to indicate whether the emotions felt by the athlete push him/her towards activation or inhibition. The results obtained are:

- 5 of the athletes recorded a low level of competitive anxiety (below 16) – meaning that they rarely have anxious moments during competition.

However:

O 2 of them score low on the facilitation dimension (below 25) – meaning that these two athletes do not often have feelings of anxiety, but when they do, these emotions are debilitating. Therefore, anxiety management sessions would be needed for these athletes for situations where anxiety may arise.

O None of the athletes scored on the facilitation size above 55, but if they had, they would have had positive, facilitating emotions. It follows that these athletes would only need activation to release facilitative anxiety for better performance in the competition.

- 12 of the athletes had a moderate level of anxiety (17-22), which means that they control their emotions well during a competition, but the level of facilitation needs to be checked to look for imbalances. And therefore:

O 5 of them scored low on the facilitation dimension (below 25), which means that if their anxiety increases in competition, the resulting emotions would be debilitating. Therefore, they would need negative emotion control sessions and anxiety control sessions.

O One athlete was at the threshold of having facilitating emotions (54) which may categorize him/her as the most mentally prepared athlete in the group since he/she has a normal level of competitive anxiety and is facilitating

O The remaining 6 athletes have a normal level of anxiety and know how to control it

- 11 athletes have a high level of anxiety (over 24), and of these:

O None had an increased facilitation level (over 55) to have constructive emotions

O 4 of them had a low facilitation level (below 25), which categorizes them as anxious athletes with debilitating, negative emotions. But we know that they need anxiety-reducing interventions.

O The remaining 7 athletes have a high level of anxiety, but normal facilitation without being debilitating or facilitating.

The results of the competitive anxiety scale compared to the level of facilitation can be better explained in Table 3.

Table 3: Level of anxiety and facilitation

Negative anxiety (5)		Normal anxiety (12)			Positive anxiety (11)	
Nevative emotions (2)	Normal emotions (3)	Nevative emotions (5)	Normal emotions (6)	Positive emotions (1)	Nevative emotions (4)	Normal emotions (7)

(Negative anxiety: negative emotions, normal emotions, Normal anxiety: negative emotions, normal emotions, positive emotions, Positive anxiety: negative emotions, normal emotions)

Non-parametric tests

Next, we will use statistical procedures to confirm/infirm the hypotheses of this paper. We will use the correlational study (Spearman correlation) to see if there are significant correlations between certain dependent and independent variables.

We will also divide the analyzed group into groups according to a criterion (age, performance level, passion, competitive experience, and first experience) in order to see if there are significant differences between them using the Mann-Whitney, U test.

To test Hypothesis 1 which seeks to see if there are statistically significant differences between the rock enthusiast group and the panel enthusiast group, the U-test was run and the results are defined in Table 4.

Table 4: Hypothesis 1

	Extrinsic motivation	Social desirability
U value	53.500	51.500
z score	2.003	-2.095
p value	0.046	0.035
Critical value of U	54.000	54.000
Effect size	0.379	0.396

The table wants to explain that by means of the Mann-Whitney test we tested whether there are significant differences between the panel enthusiasts group and the rock enthusiasts group in terms of extrinsic motivation and social desirability. The U-test value for extrinsic motivation is 53.500 and for social desirability is 51.500. The critical value for the α threshold of 0.05 and n=28 participants (the rock enthusiasts group has 13 and the panel enthusiasts group has 15) is 54. Since the calculated U-test value is lower than the critical value (53.5<54 and 51.5<54), and p<0.05 (=0.046 and 0.035, respectively), it can be concluded that there are significant differences between the two groups in terms of extrinsic motivation and social desirability. The null hypothesis is rejected. The effect size is 0.379 for extrinsic motivation and 0.396 for social desirability. Thus, hypothesis 1 is confirmed. There is a strong mean difference in intensity (r=0.379) between the two samples on extrinsic motivation. There is a strong mean intensity difference (r=0.396) between the two samples on social desirability. To test Hypothesis 2 which seeks to see if there are statistically significant differences in motivation between the junior and senior groups, the U-test was run, the results being defined in Table 5.

Table 5: Hypothesis 2

	Extrinsic motivation
U value	43.000
z score	-2.066
p value	0.038
Critical value of U	45.000
Effect size	0.390

The table explains that using the Mann-Whitney test we tested for significant differences between juniors and seniors in terms of motivation. The U-test value for extrinsic motivation is 43.000. The critical value for the α threshold of 0.05 and n=28 participants (juniors are 9 and seniors are 19) is 45. Since the calculated U-test value is lower than the critical value (43.00<45), and p<0.05 (=0.038), it can be concluded that there are significant differences between the two groups in terms of extrinsic motivation. The null hypothesis is rejected. The effect size is 0.390 for extrinsic motivation. Thus, hypothesis 2 is confirmed. There is a strong-mean intensity difference (r=0.390) between the two samples on extrinsic motivation.

To test hypothesis 3 which seeks to see if there are statistically significant differences between the first mountain experience group and the first-panel experience group, the U-test was run, the results being defined in Table 6.

The table shows that using the Mann-Whitney test we tested whether there are significant differences between the group with the first experience in the artificial environment and the group with the first experience in the natural environment in terms of extrinsic motivation and competitive anxiety. The U-test value for extrinsic motivation is 26.5 and for competitive anxiety is 45.5.

Table 6: Hypothesis 3

	Competitive anxiety	Extrinsic motivation
U value	45.500	26.5
z score	2.389	3.262
p value	0.017	0.001
Critical value of U	55.000	55
Effect size	0.451	0.616

The critical value for the α threshold of 0.05 and n=28 participants (first rock experience group is 14 and first panel experience group is 14) is 55. Since the calculated U-test value is lower than the critical value (45.5<55 and 26.5<55), and p<0.05 (=0.017, respectively 0.001), it can be concluded that there are significant differences in terms of extrinsic motivation and competitive anxiety between the two groups. The null hypothesis is rejected. The effect size is 0.451 for competitive anxiety and 0.616 for extrinsic motivation. Thus, hypothesis 3 is confirmed. There is a strong-mean intensity difference (r=0.451) between the two groups on competitive anxiety. There is a strong-very strong intensity difference (r=0.616) between the two groups on extrinsic motivation.

To test Hypothesis 4 which seeks to see if there are statistically significant differences in the level of competitive anxiety between the lower competitive experience group (under 10 years) and the higher competitive experience group (over 10 years), the U-test was run.

The results of the test are shown in Table 7.

Table 7: Hypothesis 4

	Competitive anxiety
U value	30.000
z score	2.517
p value	0.012
Critical value of U	41.000
Effect size	0.476

The table demonstrates by means of the Mann-Whitney test the existence of significant differences between the group with less competitive experience (under 10 years) and the group with more competitive experience (over 10 years) in terms of competitive anxiety. The value of the U-test is 30. The critical value for the α threshold of 0.05 and n=28 participants (those with lower competitive experience (under 10 years) has 20 subjects and the group with higher competitive experience (over 10 years) has 8 subjects) is 41. Since the calculated U-test value is lower than the critical value (30<41, and p<0.05 (=0.012), it can be concluded that there are significant differences between the two groups in terms of competitive anxiety. The null hypothesis is rejected. The difference in competitive anxiety according to sport experience, is illustrated in Table 8.

Table 8: Hypothesis 4

	Competitive anxiety
U value	50.000
z score	2.022
p value	0.043
Critical value of U	51.000
Effect size	0.382

The table demonstrates by means of the Mann-Whitney test the existence of significant differences between the group of those with below average sport experience (<=10 years) and the group of those with above average sport experience (>10 years) in terms of competitive anxiety. The U-test value is 50. The critical value for the α threshold of 0.05 and n=28 participants (the group with people below average (<10 years) sports experience has 17 subjects and the group with people above average (>10 years) sports experience has 11 subjects) is 51. Since the calculated U-test value is lower than the critical value (50<51, and p<0.05 (=0.043), it can be concluded that there are significant differences between the two groups in terms of competitive anxiety. The null hypothesis is rejected.

The effect size is 0.476 for competitive anxiety depending on competitive experience. Whereas, according to sport experience, the effect size is 0.382 for competitive anxiety. Thus, hypothesis 4 is confirmed. There is an medium intensity difference (r=0.382) according to sport experience and a strong-medium intensity difference (r=0.476) according to competition experience between the two samples on competitive anxiety [10].

Given the small group of respondents, which is due to the fact that in Romania, the community of performance climbers is small, the number of athletes and sportswomen who frequently participate in internal competitions is small, and even smaller in external competitions (for example, at the 2019 national championship in the senior category, 9 girls participated, and 6 entered the final), we will use for the correlational study, the Spearman correlation.

For testing hypotheses 5, 6, 7, 8 we used Spearman correlation, and the results are highlighted in Table 9.

The analysis of the results presented in the above table shows the confirmation of hypotheses 5, 6, 7, 8, which can be detailed as follows:

Table 9: Hypotheses 5, 6, 7, 8

	rs	p	Size effect
Anxiety - competitional experience	-0.437	0.020	0.191
Extrinsic motivation - unconscious motivation	0.434	0.021	0.188
Self-esteem - unconscious motivation	-0.504	0.006	0.254
Performance level- extrinsic motivation	-0.446	0.017	0.199

- There is a statistically significant negative correlation (with r = -0.437) between the level of competitive experience and the level of competitive anxiety (p<0.05). It follows that athletes with more competitive experience will have lower levels of competitive anxiety. The effect size is 0.191, showing a statistically significant correlation of very low to low strength [11].

- There is a statistically significant positive correlation (r=0.434) between the level of extrinsic motivation and the level of unconscious motivation (p<0.05). It thus follows that athletes with higher extrinsic motivation will have a higher level of unconscious motivation. The effect size is 0.188, showing a very low-low intensity statistically significant correlation.

- There is a statistically significant negative correlation (r=-0.504) between the level of self-esteem and the level of unconscious motivation (p<0.05). It follows that athletes with higher self-esteem will have a higher level of unconscious motivation. The effect size is 0.254, showing a statistically significant correlation of low intensity.

- There is a statistically significant negative correlation (r=-0.504) between athletes' performance level and level of extrinsic motivation (p<0.05). It thus follows that athletes with higher levels of extrinsic motivation will have better sports performance. The effect size is 0.199, showing a statistically significant correlation of low intensity [12,13].

CONCLUSION

Concerning the first hypothesis, we issue the following psychological assumptions. We would dare to say, despite some terrible accidents that have taken place on the cliff and in which prominent athletes have been involved, that this form of training in solitude, for balanced athletes, is more valuable, developing their caution and teaching them to know their limits. Conversely, on the panel, social desirability can bring with it the risk of showmanship and extravagance, when an athlete, although intuitively sensing correctly where his or her limits and capabilities lie to cross a threshold at a given point in time, may choose the opposite in the sense of skirting risk, out of demonstrativeness, extrinsic motivation and the desire to please supporters [14].

As a conclusion, we could say that passion for rock is positively correlated with intrinsic motivation, a balanced personality and authentic knowledge of physical and psychological resources at that moment of time, while passion for panel is more likely to be related to extrinsic motivation, social desirability, maintaining an image, the fact being also supported by a more vivid communication and in a here and now with the audience [15].

- Thought of in a long-term dynamic, things are not so exclusivist, as genuine athletes train on the panel for long periods in order to accumulate sufficient "psychological nourishment" provided by the admiration of others for the moments when they are about to climb the cliff and when the reminiscences of success on the panel will help them to surpass their limits [16,17].

- The results of the second hypothesis, which emphasizes the shift from junior to senior of motivation from extrinsic to intrinsic, appeals to several psychological concepts. Starting from Piaget, who describes the stages of intelligence development, the shift from childhood to adolescence and adulthood follows the same path from externalisation to internalisation of the desire for knowledge, of the perception and internalisation of the sense of danger, of the balance in the judicious allocation of resources. Juniors are dependent on the admiration of parents and coaches, on the public which in itself is happy to create young images, especially in a less developed sport in a country like ours [18]. Any junior considered a hope in Romanian climbing is greeted with joy, climbing being a sport aimed at an audience mature enough to overcome envy, malice, lack of opportunities for collaboration, promotion of non-values as is perhaps the case in other team sports or with a longer tradition and many followers.

- Climbing is a sport that is easy to enter, the environment and the circle of seniors who are frequently attached to competitions (direct participants, supporters, coaches or sponsors), capable of emotionally supporting juniors, promoting them, ranking them without them feeling blamed, pushed aside, criticised, rejected [9]. Currently, in Romanian climbing, for ages between 4 and 16 years old, perhaps extending to 18, we consider extrinsic motivation important because it supports the inner construction of the athlete, helps him/her reach and maintain the state of readiness, creates a sense of a continuum between him/her and the audience. Let's not forget those key moments when the junior is majorly dependent on the ideal match between the shouts and support in the gym and his/her internal moment when he/she is ready to step off the track. Seniors, however, are mature people who bring together multiple competitive experiences with personal life experiences from the various fields in which they are still active, and from the questionnaires administered they emerge as authentic personalities with no false selves, no false modesty, no hiding or desire to present themselves in a more favourable light [19].

- For seniors, intrinsic motivation requires dedication, composure, balance, responsibility, the ability to know how to lose, and the ability to recognize a new value emerging in your shadow or next to you, long-term planning of resources so that competition matches peak performance. Intrinsic motivation is one that is underpinned by good self-knowledge, with pluses and minuses, strengths and weaknesses both in terms of techniques used and psychological background and the ability to induce and maintain the state of readiness [20].

- Many juniors owe their success on extrinsic motivation, namely in the junior period for two athletes who have similar technical and physical competitive qualities, a higher extrinsic motivation of one (more encouragement from the coach, more involved parents, more admirers from the public on the model of sympathy) can make a significant difference in terms of a competitive result. Among seniors, intrinsic motivation is much correlated with technical development, with a balanced psyche, with a more cautious calculation of what the individual can or cannot do, each new competition being a dynamic putting the individual's personality in competition not only with others but also with his/her own expectations, in a continuum of sports training. We thus encourage the maintenance of extrinsic motivation as a stimulus up to a certain age in junior sport, which proves its usefulness up to the point where it would become an intrusion into the athlete's inner space (the athlete would be conditioned, perhaps even threatened, blackmailed, compared to others, accused of having his/her admiration withdrawn, or the situation where significant discrepancies between likes and dislikes would affect the fragile psyche of a budding athlete) [21].

- An important variable we wanted to consider in this study was the first experience of contact with the sport, as from the constructed questionnaire it appeared that for some of the athletes the first experience corresponded with their subsequent passion for rock versus panel, but for others this was not the case. The first experience, especially if it took place at an early age correlates with extrinsic motivation, support from the entourage, praise and encouragement from others, especially if there are coaches, friends maybe even parents in the vicinity involved and dedicated to the passion for rock versus passion for panel. First experience and extrinsic motivation become important when the person in question joins a lineage. Introducing anxiety as a variable in relation to first experience and extrinsic motivation could be explained as follows: when first experience encourages passion in one direction or another, extrinsic motivation supports the direction (rock versus panel), while anxiety tends to decrease when it is not consistent with passion [22].

- It is well known that accumulated competitive experience develops not only athletic techniques, but also mental skills of concentration, stability, mobility and distributivity of attention, motor memory, memory of a chain of sequenced movements belonging to a technique, as well as the ease of habituation to get into the competitive mood, to activate on command one's readiness and flow state, to make up through technique and experience the deficit of athletic performance (if that competition does not overlap with the athlete's sports form). The more complete, valuable and comprehensive this competition is, both from a tactical and strategic point of view and in terms of the development of the athlete's personality milestones (motivation, willpower, determination, preparation), the better prepared the athlete will be and will consider tenacity superior to anxiety. In other words, competitive anxiety decreases as experience in the field is gained [17].

- The hypothesis confirming the positive correlation between extrinsic motivation and unconscious motivation is based on the fact that as the athlete progresses from childhood to junior and adulthood, he/she internalizes his/her rewards and does not need to represent them in an external plane (promises, support, cups, medals, praise), but he/she has taken within him/herself an amount of pressure "sufficiently big and at the same time sufficiently little" to be able to filter between eustress and distress so as to keep his/her anxiety within limits consistent with eustress and with the possibility of physiologically determining his/her state of alertness and vigilance as an important area of the construction of the state of flow [23].

- The fine transition from extrinsic to unconscious motivation is natural in conjunction with the development of personality, as one of the coach's desires should be a filter as careful as possible in terms of the athlete's experience of feelings of guilt in the event of failure. As it is known from the research literature, the concept of extrinsic motivation can include reprimand or punishment from secondary sources when the athlete has not brought them the expected results. Conversely, unconscious motivation, in the absence of sound principles to help develop a balanced and normal personality of the athlete, can contribute to increased feelings of guilt, anxiety, low self-esteem, subjective feelings of not being good enough, which can ultimately lead to failure. This is where we should find the great art of coaches and sports psychologists in helping juniors to put a filter when they internalize aspects of extrinsic motivation unconsciously [24].

- The following hypothesis confirms the negative correlation between self-esteem and unconscious motivation. Turning to the psychological explication, we could consider as follows: athletes able to maintain high self-esteem are those less concerned with being in touch with the unconscious strand of their own motivational resources. They are those who have strengthened their facade, their competitive selves and the imago with which they interact in the sporting world, calling on the unconscious reservoir only when they wish to make contact with what once represented praise, encouragement, admiration, resource enhancement. The lower the self-esteem of a competitive athlete, the more we are dealing with an unconscious motivation in which the athlete has a severe over-ego, punishes him/herself, blames him/herself, criticizes him/herself, exacerbates his/her guilt, considers that he/she has not done enough, self-stigmatizes him/herself and can no longer find the way to reactivate his/her beneficial resources, the techniques that once proved successful, the positive mental states. Athletes with low self-esteem also lose patience and forget to think by steps, little by little, expecting the coach or psychologist to provide miraculous solutions that will free them from a new circuit of effort in order to recover both their self-esteem and their high position in the competitive rankings [25].

- As the athlete and competitive years progress, extrinsic motivation loses ground to intrinsic motivation, so that a high level of performance can only be based on strong intrinsic motivation, which in turn is the axis of the personality structure of the competitive athlete [26]. Intrinsic motivation is that which is less dependent on circumstances, it is based on the concepts of effort and patience, on the adaptation of wishes to the possibilities of the body, while extrinsic motivation is fuelled by the reservoir of wishes, hopes and expectations in someone else's mind, and from one level onwards, the performance athlete tries to create their own inner world, their own competitive 'battle' space, in which both their physical and psychological attributes and qualities are brought together.

From this point, extrinsic motivation and the mind of an outsider can give errors in terms of correctly assessing the level of performance an athlete may find him/herself at a given point in time, thus asking more or less of him/her than he/she him/herself knows he/she can give.

Abstract: *(1) Background: Human papillomavirus (HPV) E6 and E7 oncoproteins are vital for developing HPV induced penile carcinoma. The viral oncoproteins play a central role in oncogenesis by interacting with several cellular regulatory proteins, such as p16^{INK4a} and p53. Many studies suggest that these proteins showed clinical utility in predicting nodal disease, cancer specific survival, overall survival and even tumor grade. Understanding the molecular mechanism involved in the carcinogenesis of penile cancer could offer biomarkers for disease progression, treatment response and potential targeted therapies; (2) Methods: This paper is a prospective study on a group of 100 patients who underwent prostate surgery during 2013 and 2014 in the Urology Clinic of "Carol Davila" Central Military Emergency University Hospital Bucharest. They were tested for HPV by PCR and IHC (p16) methods; (3) Results: 11 cases (22%) of HPV were found in the cluster of patients tested. PCR and P16 were the HPV diagnostic tests used. In order to determine the consistency of the 2 tests, the Cohen's kappa coefficient was used at a p level < 0.05. The PCR method had a sensitivity of 81.8% and a specificity of 94.9%. The P16 method had a sensitivity of 63.6% and a specificity of 89.7%.*

Keywords: *penile cancer, p53, p16^{INK4a}, prognostic, potential therapies*

INTRODUCTION

Penile cancer accounts for less than 1% of cancers in men in developed countries, being more common in less developed areas of the world such as parts of Africa, Asia, and South America (up to 20%). Beingusually an elderly disease, the mean age of diagnosis for penile carcinoma is 60 years old. Early diagnosis is of utmost importance, this disease leading to a devastating disfigurement and advanced disease being associated with poor outcomes. Two major etiologies have been proposed for the development of penile carcinoma: chronic inflammation secondary to chronic balanitis due to phimosis and HPV-induced disease. In literature,basaloid and warty subtypes are almost always associated with HPV. Studies have demonstrated that the most common type of HPV infection is HPV 16 and 18, which occur in 60–75% of in situ and invasive tumors. In terms of HPV-induced penile carcinoma, E6 and E7 viral oncoproteins are essential for developing HPV-induced penile cancer, disrupting various cell-cycle checkpoints and apoptosis. Viral oncoproteins release the cell from p53 control, thus surviving the S phase of cellular cycle with DNA damage. Furthermore, E7 overexpression is followed by the overexpression of cyclin-dependent kinase inhibitor p16INK4a, which can be used as a biomarker for HPV-transformed epithelial cells. Studies have shown that p16INK4a overexpression is only seen in high-risk HPV genotypes. Mannweiler et al. found that in the absence of HPV infection, penile carcinoma still presented p53 mutations, indicating high proliferative activity of the cells, thus disease progression [1-4].

Researching the role that p16 and p53 have in the development of penile cancer could give somemuch-needed biomarkers for disease progression and treatment response for this aggressive disease. Furthermore, understanding the molecular mechanisms involved in the pathogenesis of

penile carcinoma can offer potential targeted therapies [5].

MATERIALS AND METHODS

Markers in penile carcinoma

Role of p53 in penile carcinoma

Encoded by TP53 gene located on chromosome 17, which is the most frequent mutated gene in human cancer, p53 is a nuclear transcription factor, having a pro-apoptotic function. Named "guardian of the genome", p53 transactivates several genes implicated in the induction of cell cycle arrest and apoptosis [6,7]. Under normal circumstances, the levels of p53 are extremely low. However, in the presence of DNA damage, p53 accumulates in the nucleus through post-translational modifications like phosphorylation or acetylation.

Depending on the extent of DNA damage, p53 can either stop the cell cycle, allowing cells to repair the DNA and then letting the cells re-enter the normal cell cycle, or if the DNA damage is beyond repair it will exert its pro-apoptotic functions inhibiting the transfer of damaged DNA to daughter cells. Through these actions p53 maintains genomic integrity.

Certain pathogens, including HPV, can affect p53 protein. HPV interacts with p53 through E6, marking the protein for proteasomal degradation by transferring ubiquitin peptides from E6AP complex (E6 binds to E6-associated protein) to p53 tumor suppressor protein. Furthermore, by biding itself to pRb, which is a cell cycle regulator, and inactivating it, E7 complements the action of E6 oncoprotein. Consequently, by releasing the cell from p53 control, damaged DNA will be transferred to daughter cells [8].

As stated above, several studies have found that HPV-negative penile squamous cell carcinomas express p53 linked to TP53 mutations [4,9,10]. Although TP53 was initially described as a tumor suppressor gene disabled by loss-of-function mutations, recently it was discovered that it harbors oncogenic potential [11]. Multiple mutations of TP53 have been discovered over the years. R175H, which is the most common mutation, leads to cell cycle progression and initiation of genes that promote cell survival.

Yoshikawa et al. found that, when overexpressed, R248Q mutation offer cells an invasive ability [12]. Other mutations found are R273C, implicated in proliferation and inhibition of apoptosis, and R282, associated with higher activity of drug-metabolizing enzymes [13,14]. Even though newly pathways and mutations are being discovered, HPV-negative penile carcinogenesis is still poorly understood [15].

Role of p16 in penile carcinoma

Encoded by CDKN2A gene located on chromosome 9 (9p21.3), p16 (also known as p16^{INK4a}) is an inhibitor of cyclin-dependent kinases (CDK) that impede cell division by slowing the progression of the cell cycle from the G1 phase to the S phase, therefore acting as a tumor suppressor. p16^{INK4a} induces cell cycle arrest and prevents cell division by inhibition of CDK4 and CDK6 and inhibition of CDK-mediated phosphorylation ofRb (retinoblastoma) protein, whose expression increases as the cell cycle progresses. Phosphorylated (inactivated) pRb dissociates from the transcription factor E2F1, allowing it to enter the nucleus, thus promoting the transcription of target genes that are crucial for transition from G1 to S phase. Through its actions, p16INK4a maintains pRb bound to E2F, denying the cell progression to S phase, thus preventing excessive cell growth.

The HPV-E7 protein, which is an oncogenic protein of HPV, can bind and inactivate Rb protein causing carcinogenesis with promotion of cell-cycle progression. Therefore,high-risk HPV positive penile carcinomas have increased cell proliferation with p16INK4a overexpression, allowing p16 to be used as a surrogate marker for HPV-E7 expression. Furthermore, it has been observed that in HPV negative penile carcinomas p16 overexpression is absent, strengthening the idea that p16INK4a can be used as a biomarker for HPV related cancers [16,17].

DISCUSSION

Several papers studied the presence of HPV and its viral oncoproteins as a prognostic factor for penile carcinoma. A mutated TP53 gene usually leads to a mutated P53 protein, rather than the absence of it. The regulatory protein MDM2 (the human homologue to the murine double minute 2 oncogene) controls the intracellular p53 concentration through a negative feedback loop. Mutant p53 protein cannot bind to MDM2, thus leading to an overexpression of p53. Studies have shown that p53 overexpression is an independent predictor of lymph node metastases. In their paper, Lopes et al. observed that patients who were HPV and p53 positive had a worse overall survival than those negative for p53, with a mean follow-up of 88.7 months. Furthermore, p53 immunoreactivity and p53 grade were associated with a higher incidence of lymph node metastasis [18-20]. Martins et al. stated in their study that p53 overexpression was associated with regional lymphatic spread, recurrence, and disease specific mortality [21]. The same results regarding overall survival of patients with HPV-induced penile cancer and positive for p53 expression were found by many authors. In their paper, Prapiska et al. observed that the survival rate over 36 months in the p53 positive group was 18%, compared with a survival rate of 60% in the p53 negative group [22]. Strengthening the idea that p53 overexpression is associated with poor survival, Gunia et al. found that the 5-year cancer-specific survival was 84% in p53-negative and 51% in p53-positive PC [23].

The role of p53 was studied in several other aspects regarding its involvement in penile carcinoma. For example, Marinescu et al. conducted a research on the association of p53 and the grading of penile carcinoma specimens. They concluded that all the poorly differentiated penile cancer cases had a positive expression of p53 oncoprotein, no matter the tumor stage. Moreover, as the tumor grading improves the expression of p53 decreases, thus, p53 was found in 91.2% of the moderately-differentiated tumors a and 72.2% of the well-differentiated tumors [24]. As stated above, in HPV-induced penile carcinoma, TP53 tumor suppressor function is suppressed by E6 oncoprotein, while simultaneous activation of pRB by E7 initiates epithelial neoplasia. Multiple studies in literature found that TP53 can have mutations in the absence of HPV infection. In HPV-induced carcinogenesis, it has been observed that TP53 function can be restored via radiation and chemotherapy. Furthermore, chemotherapy and radiation therapy resistance are mediated by permanent inactivation of TP53, namely, by mutations of the TP53 coding region, since the effectiveness chemotherapeutic agents, such as 5-fluorouracil, doxorubicin, bleomycin, and cisplatin, and radiation depend partially on p53-mediated responses. This can explain the worse prognosis regarding the overall survival of patients with HPV-negative penile carcinoma after radiation and chemotherapy [15].

Zargar-Shoshtari et al. conducted a study on the clinical significance of p53 and p16 status of patients with penile carcinoma. They found that the cancer specific survival (CSS) and overall survival rate (OS) were improved in p16-positive patients. Furthermore, they observed an association with p53 overexpression and nodal disease in p16 negative patients. They also concluded in their paper that patients who had positive lymph nodes and a double p16 and p53 negative status had a significantly worse CSS. It is known that E6 oncoprotein activation leads to a reduction in host cell p53 expression, thus cells expressing only E7 could be positive for p53, whereas cells expressing both E6 and E7 are negative for p53. Because multiple molecular and genetic pathways can lead to an overexpression of p16 and p53, it is possible to detect both in the same cancer cell [25].

It has been established that pRb is a target for E7 oncoprotein leading to an overexpression of p16^{INK4a}. Because of this, p16INK4a can be used as a marker for HPV infection. Mannweiler et al. reported in their study that lesions which were p16 negative had very low rates of HPV detection. Moreover, they stated that all p16-negative cases were positive for p53 nuclear expression and that out of 72 patients with p16 overexpression none was positive for p53(4). Senba et al. observed that in the HPV-positive penile carcinoma cases, p16^{INK4a} was positive in 61.5%, compared to 25% in the HPV-negative group, strengthening the idea that p16 can be used as a surrogate marker for HPV infection [26]. Several other studies suggested that p16^{INK4a} positivity in penile carcinoma is strongly related to the presence of high-risk oncogenic HPV genotype and that negativity can indicate an infection with a low-risk genotype or the absence of HPV infection [27-29]. In their paper, Steinestel et al. found that the sensitivity and specificity of p16^{INK4a} staining to predict the presence of high-risk HPV was 100% and 57%, respectively [30].

Regarding prognostic significance of p16INK4a expression in penile carcinoma, a meta-analysis on 323 cases was performed by Zhang et al. They concluded that p16INK4a expression is independently associated with improved CSS for patients with penile carcinoma [31]. Another study found that high-risk HPV status and p16 positivity, independent of histological tumor grade, indicated a less aggressive local behavior [29]. Sand et al. observed that patients with HPV induced penile cancer with negative p16 staining had a worse disease specific survival than men with p16-positive penile carcinoma [32].

In their paper, Martínez-Bailón et al. declared that all-cancers with p16^{INK4a} overexpression were positive for HPV DNA, but, interestingly, not all HPV-positive patients were positive for p16^{INK4a}. Several papers in literature suggested that the detection of HPV DNA is not sufficient for the attribution of HPV infection to the etiology of the cancer, transcriptional activity or the molecular signature of HPV-induced carcinogenesis needed to be proven [33-35].

The report from the International Society of Urological Pathology (ISUP) consultation conference on molecular pathology of urogenital cancers recommended the use of p16 staining in cases in which the histological features of the squamous cell carcinoma are not classical for HPV-induced cancers, especially in poorly differentiated tumors. The consensus was that p16 can be used as a surrogate of polymerase chain reaction for the identification of high-risk HPV genotypes [36].

As seen so far, p16^{INK4a} is overexpressed as an early consequence of high-risk HPV-mediated carcinogenesis. Furthermore, it has been noticed that humoral and cellular immune responses occur spontaneously against p16. This observation is the basis for creating a therapeutic vaccine using a synthetic p16 peptide to prevent the outgrowth or destroy the affected cells. Two trials tested the vaccine to asses safety and immune response (ClinicalTrials.gov Identifier: NCT01462838 and ClinicalTrials.gov Identifier: NCT01462838). The conclusion was that the vaccine was safe and that it showed strong immune responses against p16, strongly induced T cell CD4+ and humoral immune responses in all patients. Moreover, it is safe to use in combination with standard cisplatin-based chemotherapy with excellent safety and tolerability [37-40].

CONCLUSION

More common in less developed countries of the world and usually an elderly disease, penile carcinoma leads to important disfigurement and poor outcome if not diagnosed in its early stages. It is well-known that HPV induced penile cancer patients have a better outcome than HPV-negative ones. Furthermore, HPV-induced penile carcinoma with p16 positive staining have better overall survival. These findings point to the possible clinical value of HPV and p16 testing when planning the most optimal management and follow-up strategy. The gold standard for HPV detection is polymerase chain reaction, but this technique is expensive and not always available, thus, since p16 protein was found to be associated with the presence of high-risk HPV, it can be used as an alternative marker. Several studies concluded that p53 overexpression was associated with poor survival and an independent predictor of lymph node metastases. Moreover, p53 positivity was strongly associated with poorly differentiated penile carcinomas. Early results of the p16 vaccine showed that it is safe and that it can trigger a good immune response, but further studies on larger patient groups are needed.

Conflicts of interest and sources of funding

The authors declare no conflict of interest.

Evaluation of children with ADHD and their psychiatric symptoms

Peyman Hashemian[1], Fasieh Mazandarani[2], Bahare Bahmani[3], Mojtaba Ghalandarzadeh[1]

Abstract: *Background: Mental disorders, especially in children, can be manifested in different ways, which is of great importance to them, so the purpose of this evaluation was to evaluate the changes in psychiatric symptoms in children with ADHD.*

Method: This evaluation was performed as a descriptive-analytic study on 141 children with ADHD who were followed up for 6 months. At the beginning of the study and the third and sixth months after, patients' symptoms were assessed with the CBCL Behavior Checklist and the ADHD rating scale questionnaire, as well as the course of illness and association with other disorders. Finally, the data were entered into SPSS statistical software and analyzed.

Results: The mean age of the children was 5.89±0.81 years and the prevalence of males was 68.8%. Among the two treatment groups, only the mean score below the ADHD-RS questionnaire score in the non-Ritalin group at the end of the third and sixth months was significantly lower than the Ritalin group. During the study in both treatment groups, the overall ADHD-RS questionnaire and both subscales of attention deficit hyperactivity disorder (ADHD) had a significant decrease from baseline to the end of the sixth month. In relation to the CBCL behavioral checklist, the mean score of the total checklist except for anxiety/depression in the non-Ritalin group and the somatic complaints subscale in the Ritalin group decreased significantly from baseline to the end of the sixth month.

Conclusion: Based on the results observed in this evaluation, Ritalin had a significant effect on the symptoms of patients with ADHD, although these symptoms improved in both groups, however, further studies are needed.

Keywords: *attention deficit hyperactivity disorder, Ritalin, children*

INTRODUCTION

Attention Deficit Hyperactivity Disorder is a persistent pattern of inattention and hyperactivity, which is more common and severe than typical of children with similar developmental levels. While in the past hyperactivity was thought to be a devastating underlying symptom of the disorder, the general view today is that hyperactivity is often secondary to poor impulse control. Impulsivity and hyperactivity are common in today's diagnostic criteria for ADHD [1]. At present, the diagnosis of ADHD has based on the agreement of experts that three observable types include: inattentive, hyperactive/impulsive, or mixed, all manifestations of a disorder. To meet the diagnostic criteria for ADHD according to the DSM-IV-TR criteria, symptoms must be present before the age of 7 (and, according to the DSM-V, before the age of 12) [2,3]. However, the diagnosis of ADHD in many children is not made until after the age of 7, when their behaviors cause problems at school and elsewhere. To confirm the diagnosis of ADHD, impairment due to inattention or hyperactivity/impulsivity must exist in at least two areas and interfere with proper social, educational, and extracurricular activities. This disorder should not occur during pervasive developmental disorder, schizophrenia, or another psychotic disorder, and no other mental disorder is a better explanation for it [4].

Attention Deficit Hyperactivity Disorder is one of the most common psychiatric disorders in children with a prevalence of 3-7% and is 3-5 times more common in boys than girls [5, 6]. Symptoms are a persistent pattern of inattention and/or

hyperactivity and impulsive behavior that is more severe than expected for the child's age and level of development. Some children may have more active symptoms and impulsive behaviors, and some may have more inattention symptoms. According to the DSM-V criteria, the symptoms of this disease start before the age of 12 and usually exist from the age of 3. But serious problems often arise during school [7]. The course of the disease is variable and most patients recover partially, and inattention is often the last symptom to improve. However, these patients are prone to antisocial behavior, substance abuse and mood disorders, etc. [8,9].

Based on the cases stated in this section, the importance of paying attention to the association of other disorders with ADHD and evaluating the effectiveness of treatment methods on these symptoms is determined. Has suffered from ADHD.

METHOD

This evaluation was a cross-sectional-analytical and longitudinal study that was performed on children with attention deficit hyperactivity disorder, in which psychiatric changes and disease course were evaluated in this group of patients.

For this purpose, 141 children aged 5 to 7 years with ADHD were included in this study by available sampling. Patients were followed up for 6 months and every 3 months their symptoms were assessed using the CBCL Behavioral Checklist and the ADHD-RS (ADHD rating scale) questionnaire filled out by parents. ADHD Rating Scale is an 18-item questionnaire for children 5 to 17 years old. This questionnaire examines the child's behavior over the past 6 months and is completed by their parents or teacher. The overall score of this questionnaire is between zero and 54 and each item is graded from zero to 3. The questionnaire also has two subscales: signs of hyperactivity / impulsivity (including 9 questions) and attention disorders (including 9 questions). This scale has two forms of school and home, the first form is filled out by school teachers and the second form by parents. In validated studies, high validity and reliability have been mentioned for it and its psychometric properties have been comparable with other valid scales for measuring the severity of ADHD (10).

The CBCL Behavioral Checklist is also a general diagnostic method for identifying behavioral problems in children. This checklist is classified into 4 forms based on different ages that examine different aspects of behavior. Similar questions are usually categorized into syndromic subscales. Accordingly, 8 syndromes include Aggressive behavior, Anxious/depressed, Attention problems, Rule-breaking behavior, Somatic complaints, Social disorders. problems), Thought problems, Withdrawn/depressed. The two general subgroups in the CBCL Behavioral Checklist also include internalization disorders (sum of scores of anxiety/ depression subscales, deprivation/depression, and somatic complaints) and extrinsic disorders (total scores of normative and aggressive behavior subscales). In this study, children aged 5 to 7 years were included in the study who were normal in terms of IQ and otherwise did not meet the inclusion criteria. Finally, the information of all patients was entered into SPSS software version 23 for further analysis and evaluation.

Ethical Considerations

This study was approved by the ethics committee of Mashhad University of Medical Sciences. Written consent was obtained from all patients' parents to participate in this study. Participants' information was kept confidential and none of their personal details, including their first and last names, were entered into the software. All individuals were given a project-specific code and analyzed accordingly. The initial information will remain with the main executor until the completion of the project and the publication of the articles. This research was presented in the Organizational Ethics Committee of Mashhad University of Medical Sciences on 12/4/1695 under the title "Study of changes in accompanying psychiatric symptoms in children with ADHD" and No. 951040 with the code IR.MUMS.fm.REC.1395.578 has been approved.

RESULTS

A total of 141 children aged 5 to 7 years with ADHD were studied in this study. The mean age of children was 5.89 ± 0.81 years. The minimum and maximum ages of children included in the study were 5 and 7 years, respectively. The frequency of boys in the studied patients was 68.8% and the frequency of girls was 31.2%. In terms of parents' education level, most fathers with a frequency of 6.2% in the diploma and bachelor's group and most mothers with a frequency of 68.3% in the same group. Also, the mean age variable in the Ritalin treatment group was 5.86 82 0.82 and in the non-Ritalin treatment group was 5.99 ± 0.77 years. There was no significant difference between the mean age in the two general groups of drug treatment (P = 0.41) and all 4 groups of drug treatment (P = 0.67). The frequency of boys in the treatment group with Ritalin and the non-Ritalin treatment group was 67% and 73.7%, respectively, but again there was no significant difference in the distribution of sex in the two groups of drug treatment (P = 0.45). Regarding the variables of father's education level (P = 0.35) and mother's education

(P = 0.13), no significant difference was observed between the two groups of drug treatment (Table 1).

Table 1: Comparison of demographic variables in groups based on the type of drug treatment

Variables		Ritalin treatment (n=103)	Non-Ritalin treatment (n=6)	P value
Gender	Boy	69	28	0.45
	Girl	34	10	
Fathers education	Less than a diploma	42	12	0.35
	Diploma and Bachelor	60	25	
	Master's degree and higher	0	0	
Mothers education	Less than a diploma	35	7	0.13
	Diploma and Bachelor	65	30	
	Master's degree and higher	2	0	

Initially, at the end of the third month and the end of the sixth month of the follow-up of children with ADHD, the ADHD-RS questionnaire score was measured for all patients. This index between the two groups of treatment with Ritalin and non-Ritalin treatment, in none of the stages of the study, there was no significant difference between the mean score of the ADHD-RS questionnaire. However, in the Ritalin and non-Ritalin groups, the mean total ADHD-RS score and both the Attention Deficit and Hyperactivity Disorder subscales had significant changes from the beginning of the study to the end of the sixth month and the trend of these changes was decreasing (Table 2).

Table 2: Examining the trend of changes in the score of the questionnaire ADHD-RS in groups based on drug treatment

Variables	At the beginning of the study	At the end of the third month	At the end of the sixth month	P Value
Overall score ADHD-RS				
Ritalin	92/53±39/62	78/10±34/45	67/75±43/40	0/003*
Non-Ritalin	92/0±51/59	71/74±47/73	55/87±49/62	0/3
Attention Deficit				
Ritalin	31/17±13/09	32/06±12/29	28/47±11/62	0/019*
Non-Ritalin	26/71±14/26	24/58±13/93	20/74±13/91	0/003*
Hyperactivity/Impulsivitiy				
Ritalin	57/93±27/68	46/89±25/74	38/46±35/72	<0.001*
Non-Ritalin	63/57±40/20	49/86±36/79	31/05±32/23	<0.001*

The mean total score of the ADHD-RS questionnaire was significantly different between the beginning of the study and the third month, between the beginning of the study and the sixth month and also between the end of the third month and the end of the sixth month. Only the mean score of the Attention Deficit Scale was significantly different between the third and sixth months. However, no significant difference was observed in this scale between the beginning of the study and the third month, as well as between the third month and the sixth month. As can be seen in the table below, the mean score of the hyperactivity/impulsivity subscale was significantly different between the beginning of the study and the third month, as well as between the beginning of the study and the sixth month. Also, the mean score of the hyperactivity/impulsivity subscale was significantly different between the beginning of the study and the third month, between the beginning of the study and the sixth month, and also between the end of the third month and the end of the sixth month (Table 3).

In evaluating the indicators related to the CBCL questionnaire, in the subgroup of internalization disorders, which includes the subscales of anxiety/depression, deprivation/depression, and somatic complaints, the average score of all these subscales except anxiety/ depression in the non-Ritalin group and the subscales of somatic complaints In the Ritalin group, it decreased significantly from the beginning of the study to the end of the sixth month.

Table 3: Difference in Ritalin treatment group measured each time

Variables	The beginning of the study	The end of the third month	The end of the sixth month
The overall score of ADHD-RS is the Ritalin Group			
The beginning of the study	-	0.02	0.011
The end of the third month	0.02	-	0.11
The end of the sixth month	0.011	0.11	-
The overall score of ADHD-RS is the Non- Ritalin Group			
The beginning of the study	-	0.001	<0.001
The end of the third month	0.001	-	0.017
The end of the sixth month	<0.001	0.017	-
Ritalin Groups Attiude Disorder			
The beginning of the study	-	>0.99	0.256
The end of the third month	>0.99	-	0.012
The end of the sixth month	0.256	0.012	-
Ritalin Groups Attiude Disorder			
The beginning of the study	-	0.558	0.012
The end of the third month	0.558	-	0.059
The end of the sixth month	0.012	0.059	-
Hyperactivity/Impulsivitiy of the Ritalin Group			
The beginning of the study	-	0.001	0.005
The end of the third month	0.001	-	0.177
The end of the sixth month	0.005	0.177	-
Hyperactivity/Impulsivitiy of the Non- Ritalin Group			
The beginning of the study	-	0.002	<0.001
The end of the third month	0.002	-	0.03
The end of the sixth month	<0.001	0.03	-

The mean score of total internalization disorders also decreased significantly in both the Ritalin treatment group and the non-Ritalin treatment group during the study. In the subgroup of extrinsic disorders, which includes subscales of normative and aggressive behavior, the mean score of all these subscales significantly decreased from the beginning of the study to the end of the sixth month in both study groups. The mean score of total extrinsic disorders during the study was significantly reduced in both the Ritalin treatment group and the non-Ritalin treatment group. Among the remaining subscales, the mean score of attention and social disorders in both groups (either Ritalin treatment or non-Ritalin treatment) decreased during the study, which was also statistically significant. But in the subspecies of thinking disorders, only in the non-Ritalin treatment group, the decrease was significant during the study. However, the same decrease in the mean subscale score of thinking disorders in the Ritalin treatment group was not significant. The overall score of the CBCL Behavioral Checklist in the Ritalin and non-Ritalin treatment groups decreased significantly during the study (Table 4).

Based on the mean and standard deviation of sub-indices related to and comparison of subgroups related to CBCL behavioral checklist, most indices had a statistically significant relationship between the time of the beginning of the study, 3 and 6 months after the intervention. There was a statistically significant difference between Ritalin and non-Ritalin groups, so both groups had an improvement over time (Table 5).

DISCUSSIONS

In the present evaluation, it was observed that the results of the evaluation of patients using the ADHD-RS questionnaire and the CBCL behavioral checklist in different treatment groups were not statistically significant, however, these cases need to be compared with studies. Accordingly, this has been evaluated in continuation of other studies conducted in this field. In a study of 154 children with ADHD treated with Ritalin, Wang et al. Observed children for two years and ADHD-RS questionnaire symptoms at the beginning, end of month 6, end of month 12, end 18 months and the last two years have been measured. They observed that the mean age of patients in this study was 6.87. 1.04 years. 72% of the patients in this study were boys and the rest were girls. In this study, for a total of two years, the mean score of the ADHD-RS questionnaire was significantly reduced (P = 0.02). The interesting finding of this study was that the decrease in the mean score of ADHD-RS questionnaire for girls was more than boys and this difference was also significant (P = 0.01). This study ultimately concludes that changes in the signs and symptoms of the disease in children with ADHD and treated with Ritalin can vary over time depending on gender [11]. Accordingly, in this evaluation, as in the present study, it was observed that the difference between the treatment groups was not significant, although these symptoms decreased in all treatment groups during treatment. In another study with a descriptive and longitudinal structure on 79 children with ADHD, Liang et al. Observed that after 12 months of follow-up, the mean score of the ADHD-RS questionnaire and both subscales decreased significantly (P = 0.001). However, the mean score of the CBCL behavioral checklist was not significantly different [12].

Table 4: Checking the process of changes in size scores of questionnaires CBCL

Variables	The beginning of the study	The end of the third month	The end of the sixth month	P Value
Attention disorder				
Ritalin	8/19±4/24	5/90±3/57	3/72±3/40	<0.001*

Somatic complaints				
Ritalin	67/12±2/84	66/44±2/06	67/41±4/81	0/33
Non-Ritalin	67/96±4/44	67/39±4/92	66/74±4/58	0/007*
Internalization				
Ritalin	78/69±9/22	74/65±6/76	74/88±10/97	0/001*
Non-Ritalin	79/48±10/99	76/70±11/57	74/09±12/18	0/003*

The results of this study are somewhat consistent with the present study. Similar to Liang's study, in our study, both ADHD-RS and Attention Deficit/Hyperactivity Disorder subscale had a significant decrease from the beginning of the study to the end of the sixth month. However, contrary to the results of Mr. Liang's study, in this study, in relation to the CBCL Behavioral Checklist, the mean score of all its subscales, except for somatic complaints and thinking disorders, in patients treated with Ritalin significantly decreased from the beginning of the study to the end of the sixth month.

Table 5: Difference of total CBCL Score and its subgroups in Ritalin and Non-Ritalin group

Variables	The beginning of the study	The end of the third month	The end of the sixth month
Overall rating CBCL Ritalin			
The beginning of the study	-	0.001	0.004
The end of the third month	0.001	-	0.171
The end of the sixth month	0.004	0.171	-
Overall rating CBCL Non-Ritalin			
The beginning of the study	-	0.003	<0.001
The end of the third month	0.003	-	0.032
The end of the sixth month	<0.001	0.032	-
Ritalin internalization			
The beginning of the study	-	<0.001	0.002
The end of the third month	<0.001	-	0.154
The end of the sixth month	0.002	0.154	-
Non-Ritalin internalization			
The beginning of the study	-	0.002	<0.001
The end of the third month	0.002	-	0.003
The end of the sixth month	<0.001	0.003	-
Ritalin exogenous			
The beginning of the study	-	<0.001	<0.001
The end of the third month	<0.001	-	<0.001
The end of the sixth month	<0.001	<0.001	-
Non-Ritalin exogenous			
The beginning of the study	-	<0.001	<0.001
The end of the third month	<0.001	-	<0.001
The end of the sixth month	<0.001	<0.001	-

Bloom et al. also evaluated the effect of Ritalin on behavioral changes and working memory of children with ADHD and observed that after 3 weeks of intervention, children in the drug group treated with Ritalin had an average score of their ADHD-RS questionnaire. It was significantly improved, but there was no significant difference in working memory performance between the two groups [13]. Based on this, it can be said that the results of this study are similar to the present study because during the current study, both in the Ritalin group and in the non-Ritalin group, both subscales of attention deficit and hyperactivity/impulsivity of the ADHD-RS questionnaire significantly decreased from the beginning. The study lasted until the end of the sixth month.

In a systematic review and meta-analysis, Strobo et al. Found that in ADHD patients, the ratio of male to female patients in all studies was 5 to 1, and the mean age of patients in all studies was 9.7 years. The researchers found that treatment with methylphenidate reduced the mean score of the ADHD-RS questionnaire filled out by teachers. The difference between the mean scores of this variable in the Ritalin treatment group and the placebo treatment group was about 9.6 points lower (CI-6.38 to C-11.75). Finally, this systematic review has concluded that treatment with methylphenidate improves ADHD-RS questionnaire scores [14]. Accordingly, these cases differed from the present study. In the present study, in comparison between the two treatment groups, the mean score of the ADHD-RS questionnaire subscales in the non-Ritalin group at the end of the third and sixth months was significantly lower than the same scale in The group has been Ritalin. While the mean subscale of hyperactivity/impulsivity at the beginning, end of the third month and end of the sixth month was not significantly different between the two groups, this difference may be due to differences in the groups evaluated in the two studies. Finally, in another study, Nasiri et al., using the Connors Parent Questionnaire, evaluated children's behavioral records and children's continuous functioning test.

Before and after the implementation of this method, there was a significant difference in 95% confidence level. While in the case of attention deficit, impulsivity and reaction time before and after the implementation of the combined method and perceptual-motor exercises, there was a significant difference in 95% confidence level, and this result means that all methods focus on the components of attention deficit. Impulsivity and reaction time are effective that these results are almost consistent with the findings of our study [15]. Accordingly, in most studies in this field, it has been observed that there is no statistically significant difference between treatment groups, however, more studies are needed in this field to confirm these cases.

CONCLUSIONS

Based on the results observed in this evaluation, the treatment groups did not notice a significant difference in the symptoms of patients with ADHD, although these symptoms improved in both groups, however, more studies are needed in this area.

Evaluation of the effect of drug on physiotherapy methods on cytokines and chemokines of Covid-19 patients

Alieh Rezazadeh[1], Mohammadreza H. Rasanani[1], Jalal Nourmohammadi[2], Mohsen Akhondi[3], Zahra S.H. Vaeaz[4], Mahdieh H. Moghadam[5]

Abstract: *Previous investigations have demonstrated that interleukin-6 (IL-6), C reactive protein (CRP), tumor necrosis factor-alpha (TNF-alpha), in Coronavirus disease 2019 (COVID-19) patients are considerably increased, and their progressive elevation are clinical threat indicators of disease severity. The purpose of this systematic review is to evaluate the efficacy of physiotherapy, specifically chest physiotherapy, on different cytokines in Covid-19 and non-covid-19 patients. The main complications and symptoms of this virus are as follows; a dry cough, fever, and progressive dyspnea. Quickly, the coronavirus, which is named SARS-CoV-21, has spread worldwide, causing severe lung inflammation, respiratory distress syndrome, cardiac and renal injury, especially in comorbidities patients. Approximately 96% of the cases experience mild respiratory symptoms; some progress to pneumonia, respiratory insufficiency, acute respiratory distress syndrome, and multiorgan failure. The overall mortality rate per number of diagnosed cases is 4.6%; it can range from 0.2% to 15% according to age and health problems. Combination MeSH and text terms were used to perform the search strategy. Interventions in RCTs and clinical trials with or without comparison were assessed. Six studies met the inclusion criteria. Studies demonstrated that physiotherapy could have an effect on TNF-alpha, IL-6, IL-10, IL-1β and CRP.*

Keywords: *COVID-19, MeSH, CRP, TNF-alpha, SARS-CoV-21*

INTRODUCTION

Severe cases of Covid-19 have been shown to cause a mysterious condition that disrupts the immune system; Instead of attacking only infected cells, the immune system attacks healthy cells as well. This condition, known as the cytokine storm, can be fatal, but researchers have been trying to figure out how the storm works and how it can be treated. A cytokine storm is an abnormal immune response (Figure 1). This reaction is a type of systemic inflammatory response syndrome and can be accompanied by symptoms such as fever, fatigue, anorexia, joint pain, nausea, vomiting, diarrhea, skin complications, rapid breathing, palpitations, hypotension, seizures, headache, hallucinations and tremors. Researchers have now discovered in a new study to look at the progression of coronavirus infection in mice that the cytokine storm is a vicious cycle caused by the overproduction of two signaling proteins called "tumor necrosis factor alpha" (TNF) - "interferon gamma". (INF) is caused by th e body's immune system.

Together, these two proteins lead to serious conditions that can eventually lead to inflammation, organ damage, and even death. But this study in mice showed that using pre-existing antibodies to fight these proteins is an effective way to prevent death in cases of severe Covid-19 infection. The researchers noted that knowing these pathways and the mechanisms that stimulate this inflammation are very important for devising effective treatment strategies. The researchers also identified specific cytokines that activate

inflammatory cell death pathways and have significant potential for treating Covid-19 and other deadly diseases, including sepsis. Sepsis is a dangerous disease that is caused by an overreaction of the immune system to infection and gradually spreads throughout the body. Cytokines are small signaling proteins that enter the body by immune system cells to tell other cells what to do. These proteins are vital for the immune response because they can limit the spread of the virus, but some of them also stimulate inflammation. Inflammation is a natural part of the immune response in which white blood cells rush to the site of infection to fight infection.

But inflammation can also cause some autoimmune disorders, such as osteoarthritis, in which the body despite the absence of the cause of inflammation causes it. The findings of this study link the inflammatory cell death induced by the "tumor necrosis factor-alpha" (TNF)-"interferon-gamma" (INF) proteins to Covid-19. The results of this study also show that treatment Targets of this cytokine compound could be candidates for rapid clinical trials to treat Covid-19 and other often fatal disorders associated with cytokine storms. [1,2]. The coronavirus family is single-stranded RNA viruses with an approximate diameter of 80 ~120 nm. It includes 4 types: α-CoV, β-CoV, δ-CoV, and γ-CoV. Bats are the primary critical natural hosts. About 35% of their carried viruses are coronaviruses [3]. The COVID-19 is a novel coronavirus with a circular shape and approximately 60 to 140 nm [3].

In most of cases, Coronaviruses (CoVs) targeting the human respiratory system, which are the leading cause of Middle East respiratory syndrome, severe acute respiratory syndrome (SARS), and lastly, coronavirus disease 2019 (COVID-19) [4-6]. Complementary treatments, including; chest physiotherapy and therapeutic massage, are safe and noninvasive strategies that decrease the adverse side effects of disease [8]. Physiotherapy and Massage are restorative therapy involving the systematic application of pressure with the aim of improving blood and lymph circulation [7-9]. Until now, there is some lack of medical evidence for the treatment of Covid-19 in patients, and it is critical to find a low-risk and effective way to manage the Covid-19. In this investigation, we aimed to assess the effect of chest physiotherapy on the inflammatory cytokines of Covid-19 patients (Figure 2).

METHODS

Inclusion criteria for study selection

Type of study

We will include investigations related to chest physiotherapy in patients with COVID-19. we will search for investigations in English; all articles included are clinical trial and randomized controlled trial (RCT) type articles.

Type of participant

All patients with COVID-19 are included regardless of sex, age, economic status, race, and education. Children, Pregnant women, postoperative infections, and patients with severe cardiovascular and other complications are not included in this systematic review.

Type of outcome measure

The primary outcome was the influence of chest physiotherapy on the cytokines of patients.

Data collection and analysis

Selection of studies

Our investigation is in line with the Preferred Reporting Items for Systematic Reviews and MetaAnalyses (PRISMA) guidelines flow chart to demonstrate the process of selecting literature for the entire study. Before searching the articles, all reviewers debated and determined the screening criteria. After that, the two reviewers separately reviewed and screened the articles. They screened the titles and abstracts of the articles to get related articles and then removed some duplications and articles with incomplete information. We also tried to obtain the full text, and the articles were managed using EndNote software. By the end, Discrepancies were resolved by consensus. The whole process is shown in Figure 3.

RESULTS

Six investigations which included in our study, two of them assessed the effect of Tai chi in the level of insulin, insulin-like growth factor (IGF)-1, insulin growth factor-like binding protein (IGFBP)-1, IGFBP-3, and cytokines interleukin (IL)-6, IL-2, and interferon (IFN)-γ and other investigation evaluate the effect of physical therapy modalities on inflammatory cytokines and chemokines. These studies demonstrated that physical therapy modalities could significantly diminish the monocyte production of proinflammatory cytokines and proinflammatory gene expression. However, physical therapy modalities like tai chi may increase the production of anti-inflammatory cytokines.

Macrophage activation syndrome is characterized by a marked increase in proinflammatory cytokines called storm cytokines. This severe inflammation, without any therapeutic intervention, leads to severe tissue damage and eventually death of the patient. Research has shown that specific cytokines, especially TNF-α, IL-6, and IL-1β, are involved in this phenomenon. Macrophages produce large amounts of these proinflammatory cytokines when stimulated by macrophage activation syndrome. Inflammation upsets the exact balance between coagulation and fibrinolysis.

Certain inflammatory cytokines, such as TNF-α and IL-1, initiate the production of tissue factors from monocytes and macrophages, which leads to the activation of coagulation. IL-1 and IL-6, on the other hand, increase the production of plasminogen activator inhibitors. Therefore, the overproduction of inflammatory cytokines causes intravascular coagulation. Cytokine storm is a condition of the immune system in which various immune cells are highly activated and produce large amounts of cytokines; This in turn leads to excessive inflammation, which is often associated with multiple organ failure and high mortality. Inflammatory cytokines or various chemokines such as tumor necrosis factor (TNF-α), type I and II interferons, interleukins (IL-1, IL-6, CCL2 or monocyte-chemotactic protein (MCP-1), as well as cytokines Immunosuppressants such as IL-10 or β-TGF- have been implicated.

Cytokine storm has been observed and discussed in various clinical conditions such as rheumatic or blood disorders. In addition, it sometimes occurs in infectious diseases and makes the patient resistant to treatment. This is associated with the development of acute respiratory distress syndrome (ARDS), which is one of the most severe pathogenic disorders of the respiratory system and causes pulmonary edema, decreased gas exchange and a lack of lethal oxygen. It has recently been suggested that cytokine storms, particularly acute respiratory distress syndrome, are involved in and exacerbate pneumonia associated with the Covid-9 virus. Although the body of most patients with Covid-19 does not show any symptoms of pulmonary disorders, even mild ones, about 20% of patients develop severe pulmonary dysfunction. It is not clear why only a fraction of patients with Covid-19 develop severe inflammation, but the Covid-19 virus appears to infect certain types of cells, such as endothelial vessels in the lungs or cells in the alveolar wall or macrophages.

Infection of cell types may induce immune responses that trigger a cytokine storm, including macrophage activation syndrome. Severe inflammation associated with Covid-19 disease, which can be detected by coronary artery bypass grafting in Ahvaz, is clinically similar to macrophage activation syndrome. There have been reports of severe increases in IL-1β, IL-2, IL-6, IL-7, IL-17 and TNF-α in patients with severe pneumonia caused by Covid-19. It is noteworthy that the levels of IL-2, IL-7, TNF-α, G-CSF, CXCL10, CCL3 and MCP1 were higher in the plasma of patients treated in the ICU than in patients who were not admitted to the ICU.

In addition to elevated cytokines, elevated serum levels of ferritin, CRP, and D-dimer also indicate severe inflammation similar to macrophage activation syndrome and fibrinolysis in Covid-19 patients. Immunological and pathological manifestations of this disease are mainly observed in the lung, which is associated with acute respiratory distress syndrome (ARDS). Clinically, acute respiratory distress syndrome is associated with hypoxia, extensive pulmonary infiltration, pulmonary edema, and decreased lung adaptation. Which in general leads to respiratory failure. Plasma levels of TNF-α, IL-1β, IL-6 and IL-8 are elevated, indicating severe acute respiratory distress syndrome in the deceased compared to survivors. It is reported that about 20% of patients develop acute respiratory distress syndrome during Covid-19 disease, and some patients deteriorate rapidly and die.

Recent genomic studies have shown that the enzyme converter angiotensin-2 (ACE2) and serine membrane protease (TMPRSS2) are expressed at the level of type II pneumocytes and cause SARS-CoV-2 virus to enter target cells. The onset of local inflammation due to SARS-CoV-2 infection activates macrophages at that site and spreads rapidly throughout the lung. This is likely due to the abundant expression of virus receptors, angiotensin-converting enzyme 2 (ACE2) and serine membrane protease (TMPRSS2). The accumulation of immune cells accelerates the rate of pneumonia to acute respiratory distress syndrome (ARDS). In severe cases, local inflammation inside the lungs cannot be relieved, resulting in multiple organ failure and death. The result is shown in Table1

DISCUSSION

With the quick enhancement in the number of COVID-19 patients, the number of cured COVID-19 patients is increasing, and the number of patients recovering from COVID-19 is also rising. Patients with COVID-19 often experience the series of respiratory symptoms and complications. There are a few evidence that the physical therapy modalities can have an effect on the level of cytokines and chemokines through the body. All in all, chest physiotherapy or other physical modalities are noninvasive methods, which can affect Covid-19 management, especially patients in the recovery period. However, a few numbers of studies worked on the effect of chest physiotherapy on cytokine and chemokines in Covid-19 patients. Moreover, further investigations are required to evaluate the exact effect and mechanism of these therapies on Covid-19 patients to better manage this outbreak.

The researchers found that the coronavirus behaves differently, turning off genes that prevent the virus from replicating, but does not affect immune cell-calling genes, and that these genes can function normally.

This causes the virus to multiply and overproduce immune cells that invade the lungs and other organs, resulting in excessive inflammation. The team at Icon Medical School in New York says early treatment of patients should focus more on repairing the pathway blocked by the coronavirus than on inflammation. "One thing is to tell all the cells around to be amplified, and the second thing is to send the cell," Dr. Benjamin Tanveer, a virologist, and professor of microbiology at Aikan Medical School, told DailyMail.com "More professional immunity to the site of infection." Cells in our bodies usually have two groups of antiviral genes: interferons and chemokines. Interferons are messaging proteins that are released by infected cells and are named because of their ability to prevent the virus from multiplying. Chemokines are small molecules that attach immune cells to the site of infection so that they can target and kill the virus. According to Tanveer, the first set of genes control the virus for about 7 to 10 days, so the set second has enough time to prepare the immune cells for the attack. "Interferons are called 'defense's' genes, and chemokines are called 'support's' genes,".

They are neutralized and destroyed." "Even the first line of defense, the 'defense call', is often enough to completely stop the proliferation and neutralize the infection even without a second response." However, unlike the flu or severe acute respiratory syndrome (SARS), the coronavirus shuts down a number of genes and activates other genes. An animal model of a date rat was examined. In the case of coronavirus, there was a very mild response to the "defense call" genes - which prevent the virus from replicating - and a significant response from the "support call" genes.

Studies included in qualitative synthesis (n = 6)

"The combination of the two is a bad combination," Tanvir said. When they examined the lung cells of two patients with Covid 19 who had lost their lives, they found that they were giving exactly the same answer. "It begins to multiply, and the infected cells at the site of proliferation do not report the infection well, and as a result, the infection spreads to the lungs." This means that the virus is still multiplying because there are no interferons, but those cells still need to call for support. So different types of immune system cells - neutrophils, macrophages and lymphocytes - come into play, but when they arrive, there is nothing to control the viruses. "And more has reached the lungs, but the cells are calling for support."

Now, the lungs have immune cells such as macrophages and neutrophils that lead to more inflammation. Basically, the body's immune system revolves around itself. This is likely to cause cytokine storms, which occur when the body fights its own cells and tissues instead of fighting the virus. "The behavior of this virus is such that I have not seen in 20 years of studying how cells respond to viral infections.

There are two ways to treat patients. The first group consists of people who have just shown symptoms," says Tanveer.

And their test results are positive. "They can take drugs that inhibit the defense genes so that the virus can behave more like the flu,".

For those hospitalized and intubated, it is too late to use this treatment, so they can benefit from a group of drugs called interleukin-6 and interleukin-1 inhibitors. Help reduce cytokine storms and inflammation throughout the body.

Modulation of biological reactions plays an important role in improving body function following immunological challenges.

Echinacea is one of the best and most effective plants for modulating the activity of the immune system, and the results of laboratory studies and clinical experiments have confirmed this claim.

The effects of this plant on stimulating the immune system and promoting the body's defense are manifested by increasing the activation of phagocytosis, stimulating fibroblasts, increasing the activity of leukocytes and increasing the production of cytokines.

The anti-inflammatory effects of the plant are also effective in regulating the immune response in suppressing infection and preventing cytokine storms.

CONCLUSIONS

Physical therapy modalities like chest physiotherapy or tai chi can be beneficial in managing covid-19 because of their effects on cytokines and chemokines through the body. Nonetheless, further evidence is needed to evaluate the exact effect of these interventions. What is certain is that the SARS-CoV-2 virus threatens the lives of millions of people around the world. By better understanding the nature of the virus, experts have been able to prevent its widespread spread in certain parts of the world. However, no effective drug or vaccine has yet been developed. Severe cases of Covid-19 disease are often seen with acute respiratory distress syndrome, with clinical and laboratory features similar to macrophage activation syndrome. Previous studies have shown that the symptoms of macrophage activation syndrome improve with anti-cytokine therapy. So far, anti-IL-6, IL-1 and TNF therapy have shown promising results in the treatment of macrophage activation syndrome. Based on these findings, treatment with anti-IL-6 or IL-1 drugs has been performed in Covid-19 disease and has caused significant improvement in patients so far! There are currently more than 1,900 clinical trials worldwide, and it looks like these studies will soon provide a new and effective treatment for Covid-19.

Evaluation of the effects of dexamethasone in modulating breathing pattern decomplexification in rats with 2-chloroethyl ethyl sulfide induced lung injury

Sayed M.E. Behrouzi[1], Alireza Shahriary[1], Mohammad R. Raoofi[2], Mostafa Ghanei[1], Hadi E.G. Ghaleh[3]

Abstract: *Background and Objectives: Sulfur mustard is a functional alkylating chemical warfare agent that gives rise to appalling lung injury. In people with pulmonary diseases, including asthma, the complication of respirational dynamics is reduced. However, the complexity of breathing patterns in lung injury caused by chemical agents is not clear. In the current study, the outcome of 2-chloroethyl ethyl sulfide (CEES), and mustard analogue, upon breathing pattern of rats without or with treatment were reviewed.*

Methods: The interbeat interval (IBI) and respiratory volume (RV) data have been acquired from spontaneous respiration rats with lung injury by CEES using a whole-body plethysmograph. We calculated mean and coefficient of variation, alpha exponent derived from detrended fluctuation analysis (DFA), and sample entropy of IBI and RV.

Finding: Entropy examination of respiratory variation displayed reduced inconsistency (less complication) in the breathing pattern of this rat model of lung injury. The mustard analogue also led to increased lung inflammation in damaged rats. However, treatment by NAC and dexamethasone had a compelling impact on the complication of the breathing rhythm and lung inflammation of rats with lung injury.

Conclusion: Our findings show that inflammation could be the possible origin of respiratory dynamics shifting apart from the normal variation in CEES-induced lung injury.

Keywords: *2-chloroethyl ethyl sulfide, breathing pattern, dexamethasone, Inflammation, modulates, rat model*

INTRODUCTION

Mustard agents have been used in various battles since the First World War and are responsible for more than 80% of all chemical war gas victims [1]. Severe lung damage is recognized to happen in different conditions, encompassing exposure to mustard gas and its subordinates, such as 2-chloroethyl ethyl sulfide (CEES) [2]. Acute lung injury is defined as necrosis in the pharynx and epithelial detachment, bronchioles and, trachea, while long-term effects comprise of fibrosis and, in some cases, cancer [3]. Also, both animal models and human exposure data indicate the inclusion of mediators and inflammatory cells in SM-generated lung injury. After exposure of rodents to SM and CEES by intratracheal instillation or inhalation, inflammatory cells have been spotted in the higher, and lower inhaling tract [4]. Mustard sulfur causes changes in respiratory parameters and inspiratory airflow limitation [5]. However, the mechanisms involved in changing respiratory parameters are not clear. Previous studies have shown therapeutic effects of anti-inflammatory agents, including corticoste roids, in SM-induced lung injury. Wigenstam and colleagues reported that anti-inflammatory steroids, such as dexamethasone reduce the inflammation of passageway for air, lymphocyte activity, and collagen deposition within an hour following the exposure by nitrogen mustard [6]. Furthermore, short-term studies using intravenous and oral N-acetylcysteine (NAC) in patients with chemical lung injury have revealed the potency of this compound to restore pulmonary function tests with a low incidence of adverse

effects [7]. Normal respiration demonstrates fluctuating dynamics in respiratory volume and rate, arising from the complex relationship between various internal and external climate factors. This system continuously fluctuates under fragile stability to maintain adjustability to stimuli [8]. Pulmonary diseases have a variable medical disorder and show complex behavior, which might be related to a change in the dynamics of the respiratory system toward either too irregular or too regular [9]. Investigating breathing pattern complexity is beneficial to the determination of disease control, severity, blockage, and response to treatment in pulmonary patients. Therefore, understanding the changes in breathing pattern can be contributive to our understanding of the pathophysiology of lung injury and might provide new perception to establish new interventions and curing strategies [10]. In this study, we hypothesized that the complexity of the respiratory pattern is decreased in rats with CEES-Induced lung injury, and since these animals had inflammation, the respiratory pattern could be brought close to natural conditions using an anti-inflammatory agent. To assess this, we compared the complexity of the respiratory dynamics among control and CEES-induced lung injury rats and also reviewed the outcome of N-acetylcysteine and dexamethasone on treating rat models of pulmonary injury.

METHODS

Experimental groups

The Ethical Committee of Baqiyatallah University approved all the protocols.

Specific pathogen-free male Wistar rats, weighing 250 ± 20 g, were randomly splitted into five groups (n = 6 for each group): (i) Vehicle group, which received a single intratracheal dose of vehicle (60 µL of ethanol + 340 µL phosphate-buffered saline (PBS)); (ii) CEES group, a single dose of CEES was intratracheally instilled to the second group (Sigma Chemicals, MO) (2 µL/rat or 6 mg/kg in 58 µL of ethanol + 340 µL PBS) [11] (iii) CEES+PBS group, during intraperitoneally handeling of PBS was (i.p.) one hour after instillation of CEES; (iv) CEES+NAC group, to which NAC was handeled intraperitoneally (i.p.) 1 hour after instillation of CEES (20 mg/kg body weight of NAC in in 400 µl PBS) [12] and (v) CEES+Dex group, in which Dexamethasone was administered intraperitoneally (i.p.) 1 hour after instillation of CEES (10 mg/kg body weight of Dexamethasone in 400 µl PBS [6] Intraperitoneal ketamine (100 mg/kg body weight) was used for intraperitoneal xylazine and anesthesia (13 mg/kg body weight) was used for sedation when required [12].

Recording of respiration

In all groups, respiration was recorded a day before administrating the drugs and 24 h after the challenge. Conscious rats respiration was recorded by a purpose-built whole-body plethysmograph [13]. In short, this comprises of an animal chamber made of a clear Plexiglas cylinder (wall thickness 5 mm, volume 1.32 L, length 300 mm, i.d. 75 mm) with inversely straighten outlet and inlet ports in each wall. To avoid any increase of CO_2 in the plethysmograph, the air in the room was repeatedly pumped into the chamber at a controlled flow rate (4 L/min). A plastic Yconnector was placed at a distance of 10 cm from the outlet of the chamber, and one of the exit ports was linked to one input of a differential pressure probe (MPXV7002DP, Freescale Semiconductor Inc.), while the other input exposed to room air. The plethysmograph chamber was also connected to one input of a CO_2 sensor (MG811, Sandbox Electronics Inc.), through polyethylene tubing connected to a second exit port of the Y-connector, and another input of the CO_2 sensor was exposed to room air. Each test incorporates approximately 15 min early recording period (as the acclimatization time) succeeding by a 60-min main recording period.

Breathing Rythm examination

By using a PowerLab A/D converter (ADInstruments, Sydney, Australia), the breathing signals were digitized at a 10 KHz sampling rate and exhibited on ChartPro 7.0 software. For breathing pattern analysis, a minimum artifact with 20 minutes of data was selected. For calculation of the time-series of respiratory volume (RV) and inner breath interval (IBI), a custom program written in MATLAB software was adapted. Identification and verification of the peaks for each respiratory signal were carried out. Subsequently, the amplitude of peaks and the peak-to-peak time intervals were considered as the RV and IBI series, respectively. Irregularity of breathing pattern was quantified by calculating the sample entropy (SampEn) as an index displaying the degree of complexity. The negative natural logarithm of the conditional eventuality is SampEn that periods within a physiological-series and match within tolerance r for m points will also match for m+1 points [14]. Our calculation showed that SampEn of RV and IBI series are equivalent to 2 for m and 0.2 for r, using MATLAB code available from the physionet (http://www.physionet.org). DFA method can be used for evaluating fractal-like temporal structure of a time series. In this technique, the root mean square of the variation of the combined and detrended data is evaluated within time windows of different sizes and then plotted against window size on a log±log scale. A lineal relationship among log (window size) and log (oscillation) show the attendance of self-similar time-series [15]. The alpha (α) scaling exponent is the slope of this line. This parameter demonstrates the relationship within the time-series inconsiderate of the scale.

Bronchoalveolar lavage cells and Histological assessment

At 2 h after respiration recording, rats were anesthetized and 3 ml of sterile physiological saline was slowly instilled and considerately pulled out into the syringe (3 times) through the endotracheal. Samples were centrifuged, and total cell count was applied on cytocentrifugation prepared stained with Giemsa stain and, BAL cytospin samples (cytospin 3, Shandon Instruments, Pittsburgh, PA) [13].

After BALF collection, animal lungs, which had been removed earlier, were settled in formalin solution, embedded in paraffin, and slashed into 5-lm-thick slices. For identification of airway infiltration of inflammatory cells, the animal lung slices were stained with haematoxylin and eosin (H&E).

For lung inflammation measurement, the percentage of inflamed area to total lung area was considered in H&E stained lung sections [16].

Statistical analysis

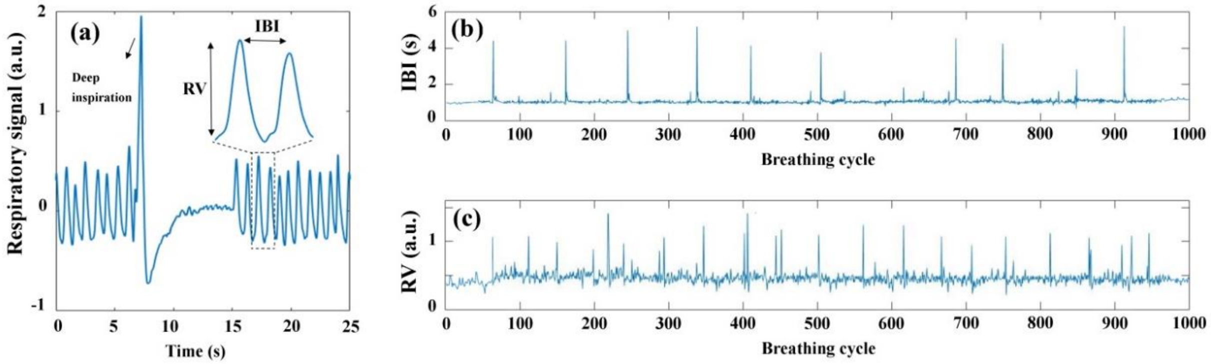
For statistical analysis of data, GraphPad Prism V6.0 (GraphPad Software, San Diego, CA) was used. The significance of changes in BALF cells, the breathing pattern, and histological among groups were compared with a one-way ANOVA with a Bonferroni post-test. Results have been introduced as mean ± standard error of the mean (SEM). P-values less than 0.05 were contemplated statistically important.

RESULTS

Lung inflammation analysis

Rats with lung injury caused by CEES (CEES group) had significantly higher levels of total BAL inflammatory cells and airway inflammation ($p < 0.001$) (Figure 1) compared to control group. However, airway inflammatory cells and total inflammation were significantly decreased in CEES group compared to CEES+NAC group ($p<0.01$ and $p<0.001$, respectively) (Figure 1). These parameters also displayed significantly lower measurements in rats of CEES+Dex group compared to CEES group ($p<0.001$) (Figure 1).

Figure 1: Breathing pattern in a representative rat. (a), Representative pieces of the breathing signal exhibit the inter-breath interval (IBI) and respiratory volume (RV), as well as deep inspiration. Original ("raw") IBI (b) and RV (c) time series during 20 min of respiration in a representative rat.



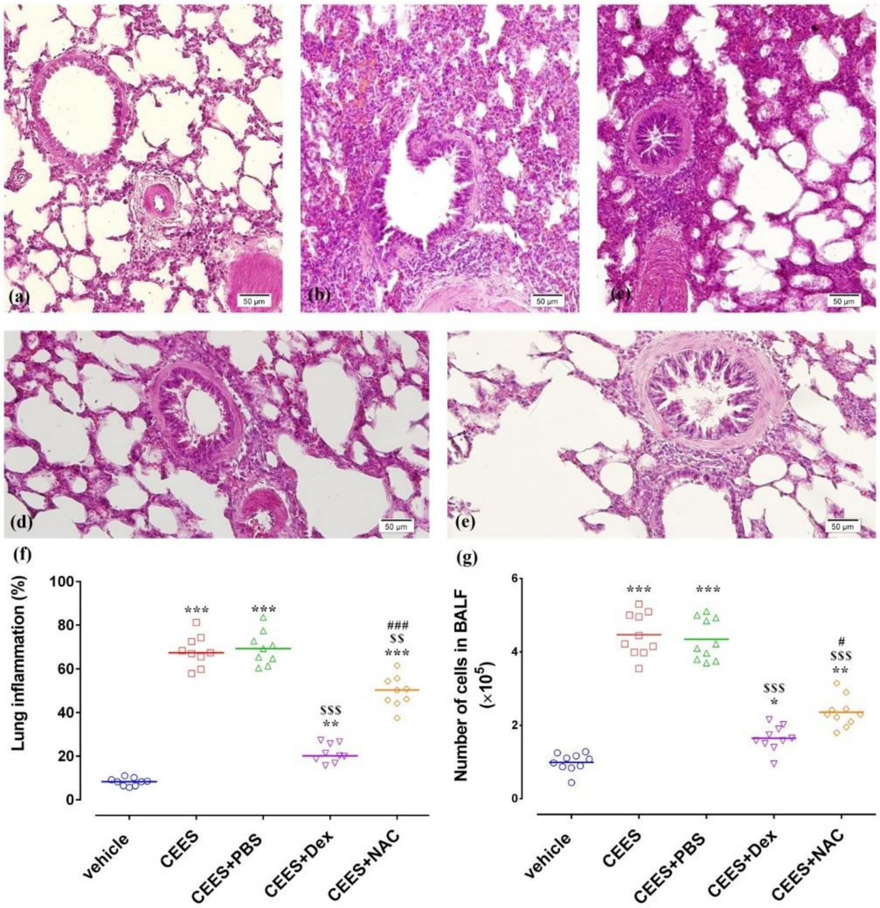
Breathing pattern analysis

The mean respiratory rate (RR) of CEES group was considerably higher compared to the vehicle group ($p < 0.001$). However, there was no significant difference in the coefficient of variation (CV) of the RR (CVRR) between the groups ($p > 0.05$). The mean of RR in CEES+NAC and CEES+Dex groups had significantly decreased compared to CEES group ($p < 0.001$) (Figures 2a and 2b). The mean of respiratory volume (RV) and coefficient of variation of the RV (CVRV) significantly decreased and increased in rats with lung injury by CEES as compared with the vehicle group, respectively ($p < 0.001$ and $p < 0.05$). However, RV and CVRV partially decreased in rats treated with NAC and dexamethasone compared to CEES rats ($p < 0.05$) (Figures 2e and 2f). The index of the irregularity for the Sample Entropy of IBI (SampEnIBI) indicated a significant decrease in CEES group compared with the vehicle group ($p < 0.001$). Similarly, this index has decreased in treatment groups ($p<0.05$). The SampEnIBI of CEES+Dex group significantly increased compared to other groups that received CEES ($p < 0.05$) (Figure 2c). Nevertheless, no notable discrepancies were discovered in SampEnRV among the experimental groups ($p > 0.05$) (Figure 2g). In the CEES group, an index of self-similarity for the slope of detrended fluctuation analysis of RV (DFARV), was greater than the vehicle group ($P < 0.01$).

This index of self-similarity had significantly decreased in animals of CEES+NAC and CEES+Dex groups as compared with CEES rats ($p < 0.05$) (Figure 2h).

Nonetheless, among the experimental groups ($p > 0.05$) (Figure 2d), DFAIBI time-series disclose no significant difference.

Figure 2: Effect of administration of NAC and dexamethasone on lung inflammation and bronchoalveolar lavage (BAL) inflammatory cells in CEES-induced lung injury Hematoxylin and eosin (H & E) staining to identify the lung inflammation (Scale bar 50 µm). Data were analyzed by a one-way ANOVA, with the Bonferroni post-test. * $p<0.05$, ** $p<0.01$, and *** $p<0.001$ compared to vehicle, \$\$ $p<0.01$, and \$\$\$ $p<0.001$ compared to CEES, # $p<0.05$, and ### $p<0.001$ compared to Dex. (a) vehicle group, (b) CEES group, (c) CEES+PBS group, (d) CEES+Dex group, (e) CEES+NAC group, (f) graph of lung inflammation, (g) total inflammatory cell.



DISCUSSION

Biological functions are intricate and based on a complex feedbacks and network of nonlinear dynamics [9,16]. Physiological variables fluctuate consistently under imbalanced steady-state conditions to retain compatibility to internal or external stimuli [10]. Similar to other physiological systems, the respiratory system is stable and fluctuates under normal conditions. A change in dynamics of a system towards either too irregular or regular may be associated with diseases such as asthma and COPD [10]. Analysis of breathing fluctuations complexity is non-invasive technique and permit us to scrutinize the integrity and adaptability of the respiratory control system. Moreover, this method of analysis has the potential to predict prognosis, severity, and controllability of lung diseases [17].

Evaluation of respiratory dynamics in an animal model of CEES-induced lung injury by complexity analysis of both volume and respiratory rate was carried out. In this animal model, respiratory rate and respiratory volume increased and decreased, respectively. These results are consistent with the previous study where chemical war victims experience cough, dyspnea, tachypnea, and chest pressure after several hours of SM exposure [18]. Some researcher demonstrated that minute volume decreased following sulfur mustard inhalation in guinea pigs [4]. Reduced SampEn values in the IBI time series of rats with lung injury shows higher regularity or low complexity in respiratory dynamics. These findings are consistent with the improved regularity of respiratory pattern observed in other pulmonary diseases such as asthma [19,20]. Previous studies have reported increased variability and α exponent of peak expiratory flow affiliated with the inadequacy of treatment in asthmatic and COPD patients [21,22]. These findings raise the possibility that higher α exponent delineates a firm and deterministic use in lung function [10]. Higher respiratory volume variability (CVRV) corroborates with the reports of respiratory volume variability in other pulmonary diseases such as asthma [16]. Nevertheless the specific pathophysiological mechanisms underlying the reduced complexity of respiratory dynamics in CEES-induced lung injury is not still thoroughly unveiled. Understanding the basis of such variable manner may lead to developing treatment strategies and better-targeted intervention in lung injury by CEES and Sulfur Mustard.

Sulfur mustard (SM) is highly poisonous to the pulmonary system, causing both chronic and acute effects encompassing airway inflammation, obstructive disease, bronchitis, and acute respiratory distress syndrome. Therapeutic Strategies for mitigating SM-induced lung Injury include antioxidants, anti-inflammatory agents, surfactants, and protease inhibitors [24]. In the present study, we reduced lung inflammation and the fluctuation of the breathing pattern by applying dexamethasone and n-acetylcysteine, where glucocorticoid proved more effective than NAC. In other words, inhibiting the inflammation process brings the complexity of respiration closer to normal conditions. It has been assumed that sulphur mustard toxicity is related to lung inflammation, and few of their symptoms may be owing to the permeation of inflammation on the nervous system. In addition, in inflammatory pulmonary diseases such as asthma, it has been shown that influenced inflammation in the nervous system [25,26]. There is some evidence to suggest that peripheral inflammation related to airway allergy may vary the immunologic state of the central nervous system (CNS), such as increased intracerebral levels of IgE and IgG. Furthermore, there is experimental evidence of neuroplasticity and brain inflammation in the nucleus tractus solitaries in animal models [25]. Therefore, regarding these changes in inflammation, the inherent properties of the central nervous system could change and causes the alteration of the respiratory system towards reduced irregularity [16]. However, we did not examine peripheral or central neural activity in the present study, and these subjects can be regarded in next studies.

CONCLUSIONS

The cycle-by-cycle changing of respiratory pattern and volume in rats were examined, and reduced complexity of breathing rhythm in a rat model of CEES-induced lung injury was revealed. According to the results of the respiratory complexity analysis, among the different treatments, dexamethasone had a greater therapeutic effect on breathing pattern decomplexification than NAC. It appears that inflammation processes may be the cause of shifting the respiratory dynamics in this model of lung injury. Future studies are needed to characterize the role of inflammation in decomplexification of breathing pattern and determine the central or environmental factors involved in inflammation in chemical-induced lung injury.

Evaluation the impact of occupational anchoring and organizational commitment on improving efficiency

Amir Ramezani[1], Ali A.A. Esfahani[1]

Abstract: *Background and Aim: One of the most effective ways to improve efficiency in organizations is human resources management. Job Anchors and Organizational Commitment are constructs having important implications for human resources management practices, especially in efficiency. The purpose of this perusal was to study a structural equation model (SEM) of the impact of job anchors and organizational commitment on efficiency in a military hospital.*

Methods: The statistical population of this study was the personnel of a military hospital, which gathered accomplishing simple random sampling method. As a result, the research used two hundred and thirty questionnaires so to analyse, accomplishing as survey was developmental-applied, that was, requirement data with questionnaires. To measure efficiency, organizational commitment and job anchors variables respectively the Persian version of Hersey & Goldsmith, Meyer & Allen, and Schein questionnaires standard were used. In order to test the research conceptual model, structural equations modelling based on partial least squares method was used, and the model was analysed using AMOS statistical software.

Results: The results of data analysis demonstrated that hidden variables such as organizational commitment, job anchors, and efficiency had acceptable convergent validity, and the fitness of the conceptual model was confirmed. Based on the research model analysis, organizational commitment did not have impact on efficiency, and job anchors had a positive and significant impact on efficiency. Eventually, the modified model showed that organizational commitment variable moderates the connection between job anchors and efficiency.

Conclusion: In light of the findings of this research, managers of military organizations should develop programs to create and improve organizational commitment in personnel. Furthermore, they should pay attention to employees' characteristics and the proportion of their occupation with job anchors in cases of changing and promoting employees. Implementing aforementioned items will have a positive impact on improving the efficiency of military organizations.

Keywords: *job anchors, organizational commitment, efficiency, SEM, military hospital*

INTRODUCTION

Nowadays, human resources are the most valuable asset of any organization and a factor of survival in competitive levels of business, helping organizations achieve their goals. Thus, human resources management are considered a challenging task whose main goal are to improve employees’ efficiency and increase organizational performance in the long run. Efficiency as a philosophy of life and improvement strategy is considered as improvement, prevalent goal, and important organizations. In fact, improving efficiency is the main goal of any organization so that its promotion strategy encompasses all units and levels of the organization. Efficiency, mentioned in the literature, is defined as "the amount of services or products that an employee produces over a period of time with an emphasis on quality. The National Efficiency Organization of Iran defines efficiency as the culture of a rational attitude towards a better and transcendent life and work. Employees’ efficiency, ultimately leading to desirable organizational performance, is a key index of organizational success, and since performance measures an organization's competitiveness, Emphasis on efficiency seems to be a requirement for management. In addition, efficiency is an important factor in identifying profits, for recognizing potential opportunities

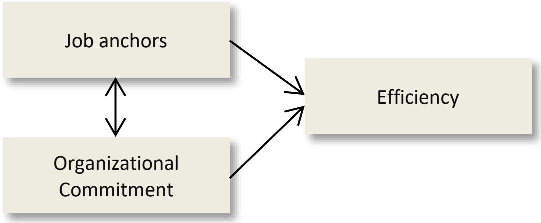
for organizational success in business, with determining the index for employees' reward and a way to appreciate hard work. Efficiency measures the efficiency of using organizational resources in order to obtain specific outputs.

In this research, the "ACHIEVE" model has been used to measure efficiency. Hersey and Blanchard, i.e., help managers to determine efficiency problems and edit strategy to solve them, developed this model. This model consists the main and influential factors in manpower performance including seven variables: ability, realization, organizational support, motivation, environmental compromise, validity, and evaluation and feedback. Organizational commitment: Organizational commitment has attracted considerable attention in the literature since various studies have emphasized the ramifications of organizational commitment, including occupational behavior and performance. A number of behavioral cues such as learning, thinking, perception, motivation, and organizational commitment are considered as the most important criteria for evaluating employees' behavior in the organization. Luthans stated that employees' commitment to an organization can be measured by their positive desire to remain an active member of the organization, their willingness to sacrifice responsibilities, and tasks at their best to do, and their acceptance reflected on the value of organizational goals. Past studies have shown that organizational commitment plays a conspicuous role in influencing employee efficiency, That is, researchers examined the connection between organizational commitment and employees' performance and found a positive and significant connection between the two variables. IN view of these studies, high levels of organizational commitment prove the success of an organization in human resources management, ultimately leading to improved performance and high employees' efficiency. Allen and Meyer model [11] asserts that despite of the extensive research being on organizational commitment, there is no consensus among management experts on the concept of organizational commitment and its focal points, having led to the emergence of different models of organizational commitment. In their view, organizational commitment has three distinct dimensions, including emotional commitment, continuous commitment, and normative commitment. Career anchors: The concept of career path as a link between organizations and the people working for them, examined from both internal and external psychological aspects. External career path includes jobs and situations through that a person progresses and is defined as organizational indicators of career path, whereas internal career path is the tendency of employees to orient or career anchor. Actually, just as sailors anchor to keep a ship afloat, so do people anchor to stay afloat.Bidabadi et al. [13] take for instance, anchor in their study shows that oxidizer and fuel are distinctly injected into a system, and before the reaction area are not mixed, in counter flow of combustion.Bidabadi et al. [14] take for example, anchor is in the burning lycopodium particle involving vaporization and drying processes in non-premixed flames of non-adiabatic combustion.Bidabadi et al. [15] another example of anchor is that single-fuel case operated by combustion of lycopodium whereas dual-combustion case is initial level. Jahromi et al. [16] final example of anchor is that this research down and up drafts gasifiers have been simulated by Computational Fluid Dynamics models to expand the process of gasification in two-dimension.Therefore, people try to establish their talents, abilities, and requirements and attitudes by making changes in their career path. Career anchors or career aspirations are specific patterns of talents, capacities, motivations, attitudes, and values imagined by the individual that guide and establish a person's progress after several years of experience and feedback from the real world. These career aspirations are aspects of a job or career path that motivate people and make them reluctant to quit when they accept a job. In addition, job anchors put forward the idea that most people do not want to limit themselves to a particular field [17]. Based on previous studies, career path anchors explain the fit between employees' job orientations and work environment, which will lead to job satisfaction, increase employee commitment and performance [18-20]. Nowadays, efficiency and identifying the effective factors is one of the management concerns in any organization, so that experts in this field consider improving efficiency as one of the vital goals of any organization [21]. This is important in healthcare organizations, such as hospitals, for the use of specialist human capital. Because governments spend significant amounts of GDP annually on defense and military organizations protect a country's national interests, independence, and security, being at the forefront in times of crisis, efficiency in military organizations is more important than in other organizations [22]. A review of the subject literature showed that efficiency studies are interesting topics for managers. In the study of Bahadori et al. [23], the factors affecting efficiency were extracted by reviewing previous studies and they present a model with 10 components, including organizational culture, mental growth, intellectual, and personality, organizational support, motivation, education, personal health, performance appraisal, job clarity, ability, and environment. Jafari and Tehran [22] identified the effective factors on efficiency in a review study whom they evaluated. They identified effective factors on efficiency including individual factors consisting motivation, mental development, personal health, ability and organizational environmental factors containing organizational support, job clarity, environment, management style, education, culture, and performance appraisal. Ali Akbar Esfahan et al. [24] in their study on the connection between intellectual capital and efficiency of human resources and occupational performance from the perspective of military hospital staff showed that intellectual capital has a positive and significant effect on efficiency.

Given that thus far limited studies have been conducted on the effect of organizational commitment variables and job anchors on efficiency, especially in military organizations, this study tried to investigate this issue (Figure 1).

Figure 1: Conceptual model of research



METHODS

The present study was conducted as a cross-sectional survey study in a military hospital. The target population of this study consists of all hospital staff with more than 3 years of work experience. Due to the limited population of the study, the sample size was determined to be 225 based on Morgan table and Cochran's formula. Owing to the possibility of non-return of a number of questionnaires or their incompleteness, a drop of 10% was considered for the sample size. Finally, 248 questionnaires were distributed among the samples, completed at the end of 230 questionnaires and provided to the research team. The criterion for entering the samples was more than 3 years of work experience and the criterion for leaving was the incomplete or unconventional answers of the distributed questionnaire. A simple random method was used for sampling, so the instrument used in this research was a four-part questionnaire. The first part included demographic information including gender, age, marital status, education, occupation, employment status, and work experience. The second part included the efficiency questionnaire, the third part included the organizational commitment questionnaire, and the fourth part included the job anchor questionnaire.

Hersey & Goldsmith Efficiency Questionnaire: this Persian and standardized questionnaire [25] contains twenty-six questions. The scale of answering the questions was in the form of a five choice spectrum very low, low, medium, high, and very high and the whole questionnaire included seven constructs ability, comprehension, organizational support, motivation, feedback, credibility, and adaptability. The reliability of this questionnaire in the present study was obtained by Cronbach's alpha index of point eight nine one.

Meyer & Allen Organizational Commitment Questionnaire: this Persian and standardized questionnaire [26] contains twenty-four questions. The scale of answering the questions was in the form of a seven choice spectrum strongly disagree, relatively disagree, slightly disagree, have no opinion, slightly agree, partially agree, and strongly agree. The whole questionnaire included three being a structure emotional commitment, normative commitment, and continuous commitment. The reliability of this questionnaire in the present study was obtained by Cronbach's alpha index of zero point eight zero one.

Schein Job Anchor Questionnaire: this Persian and standardized questionnaire [27] contains forty questions. The scale of answering the questions was in the form of a four choice spectrum never, rarely, often, and always. The whole questionnaire consisted of eight structures technical-applied, general management, autonomy-independence, security-stability, Creativity-entrepreneurship, service and self-sacrifice, and pure challenges and lifestyle. The reliability of this questionnaire in the present study was obtained by Cronbach's alpha index of zero point eight six-four.

Statistical methods and structural equations modelling were used to analyse the data in this study. Quantitative indices, percentage, and mean indices, standard deviation, were used for descriptive tables and reporting of qualitative variables.

Given the normality of the data distribution, assessed by the Kolmogorov-Smirnov (K-S) test, Pearson correlation coefficient index was used to determine the correlation among quantitative variables.

Structural equation modelling was used to evaluate the research model and the connection between the main research variables. The level of statistical significance in this study was considered zero point zero five,

That was, SPSS software version twenty first was involved to prepare descriptive tables and statistical analyses and AMOS software version twenty first was used to analyse structural equations modelling.

Observance of ethics standards in research

All individuals were reassured about being free to participate in the research and not being forced to continue participating in the research**.**

RESULTS

In this study, two hundred and thirty personnel of a military hospital participated. Forty eight point thirty percent of the participants were male and fifty one point seventy percent were female. Seventy one point seven percent of the participants were married, sixty three point nine percent of all participants had a master's degree, and-six point one percent had a bachelor's degree or lower. The average age of participants was thirty-two point twenty two years with a standard deviation of four point sixty seven years and the average age of work experience was eleven point eighty one years with a standard deviation of four point three years (Table 1).

Table 1: Summary of demographic information

Variable		Number	Percentage
Sex	Male	111	48.3
	Female	119	51.7
Marital Status	Bachelor	65	28.3
	Married	165	71.7
Education	Bachelor of Science and Lower	83	36.1
	Master of Science	147	63.9
		Average	**Standard Deviation**
Age		32.29	4.67
Occupation history		11.81	4.30

The results of this study showed that the score of job anchors and organizational commitment do not have significant connection with demographic variables, P >0.05. In this study, there is a significant connection between efficiency score and demographic variables of age and work experience, P <0.05. Therefore, that with increasing age and work experience, the efficiency of individuals for the organization decreases significantly (Table 2).

Structural equations modelling was used to answer the question whether there is a significant connection between job anchor variables and organizational commitment and if these two variables affect the efficiency score of individuals in the organization (Figure 2).

Figure 3: Structural model of final modified (connection between job anchors and efficiency with the effect of variable moderating of organizational commitment

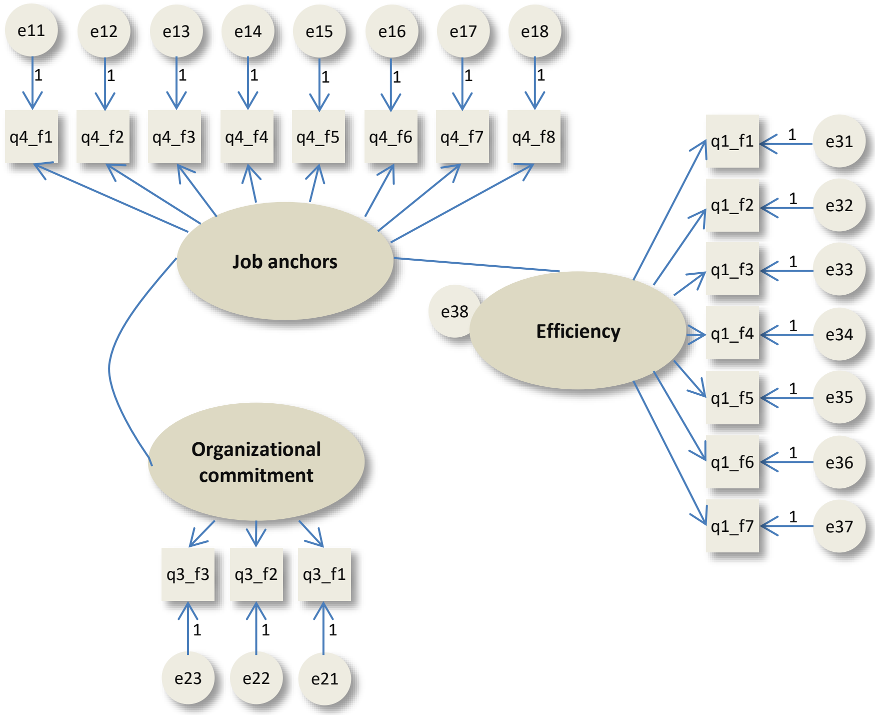

Table 2: Commitment connection of organizational and efficiency with age and occupation precedent

Variable	Efficiency	
	Pearson correlation	P significant
Age	-0.371	0.033
Occupation history	-0.303	0.046

Structural model studies (Figure 1) show that the model is significant, P <0.05. Considering that the Chi-Sq./df index is a value between two to five and the GFI, AGFI, CFI and NFI indices are greater than zero point nine and the RMSEA index is less than zero point one, indicating a good fit of the model has it (Table 3).

Table 3: Summary of fitting indicators of structural model of connection between organizational commitment, job anchors, and efficiency

Index RMSEA	Index NFI	Index CFI	Index AGFI	Index GFI	Index Chi-Sq/df	P Significant	Degrees of Freedom df	Ki Do Chi-Sq
0.066	0.924	0.941	0.900	0.912	3.85	0.008	133	512.58

Considering the significance of the coefficients of each questionnaire and their structures and the connections among variables, the results showed that job anchors separately have a significant effect on efficiency, P <0.05, but organizational commitment alone on Efficiency do not have significant effect, P >0.05. Considering the significant correlation between organizational commitment and job anchors, P <0.05, it can be seen that organizational commitment acts as a moderating variable. In other words, the connection between job anchor and efficiency can be justified when the effect of organizational commitment variable is applied to the model (Table 4). Finally, Figure 1) can be modified and explained as Figure 2 and Figure 3.

DISCUSSION

Efficiency and effectiveness are economic requirements for every country whose goal is economic development, such as Iran. Hospitals in all countries account for a significant share of resource consumption in the health sector. Because resources are limited, maximizing efficiency in military hospitals allows resources to be best distributed in this area. As problems increase and organizations become more complex, the need for better solutions based on the role of job anchors and organizational commitment to efficiency in military organizations is becoming increasingly important. Therefore, in the present study, the researcher decided to provide a model with a broad perspective on the impact of job anchors on job satisfaction, organizational commitment, and efficiency in military hospitals from the perspective of a military hospital staff. The research findings based on structural equations modeling indicated that the research variables such as: organizational commitment, job anchors, and efficiency had acceptable convergent validity.

		Correlation		**P Significant**
Job Anchors ↔ Organizational Commitment		-0.202		0.038

The model is acceptable since the fit indices of the model were generally proportional; in other words, based on the available indicators, the fit of the model was confirmed. According to the results, there is a significant correlation between age and work experience with efficiency. Since this coefficient is negative, with increasing age, work experience, and efficiency decreases significantly. Organizational commitment did not show a significant connection with demographic variables; also, there is a significant correlation between age and work experience with organizational commitment; in other words, with increasing age, work experience, and organizational commitment decreases significantly. Analysis of the research model showed that organizational commitment do not have significant effect on efficiency; thus, this result is similar to a number of previous studies [28,29] and contradicts some others [30].

On the other hand, the results showed that job anchors would have a great impact on human efficiency; the results indicate a positive and significant correlation between organizational commitment and job anchors, having been obtained in other studies.It can be concluded that job anchors will have a beneficial effect on efficiency by synergizing the effect of organizational commitment; however, none of the structures showed a significant connection with demographic variables. Hence, no significant correlation was found between age and work experience variables with job anchors, none of its structures. According to the results of this study, every organization should pay special attention to job anchors, in particular, when it seeks change and needs to evaluate the strengths and weaknesses of its manpower. Furthermore, it can be said that differences in job anchors will lead to diversifications in the likelihood of career advancement. By increasing information about these non-financial incentives, organizations can explain effective approaches to their employees' career development.Job anchors show the reasons why people have progressed in their careers as a pattern. This model explains why and how an individual's interactions with the organization's job anchors affect work and job satisfaction, and job orientations provide a way to understand motivational factors in job decisions. Analyzing the job anchors of individuals helps organizations redesign jobs (to meet the needs of individuals) and plan job changes. Finally, in light of the evidence of this study, committed employees help organizations to improve efficiency by choosing the appropriate job anchors.

This study is one of the first studies on the impact of job anchors and organizational commitment on efficiency and since the statistical population is limited, the generalization of results should be done with caution. Moreover, some results are inconsistent with other previous studies conducted abroad, so it is suggested that the model proposed in this study be examined in other studies for greater validity.

CONCLUSION

In view of the general overview of the results of the present study, designing the knowledge structure at all, levels of military hospitals in the country will be effective in improving and efficiency of these organizations and in this regard, staff managers as producers and national knowledge capitals have important role. Therefore, it is necessary for senior managers of military hospitals in the country to focus more on these components: namely organizational commitment, efficiency, and job anchors in order to implement this system in their organization and take full advantage of it.One of the first activities that should be considered by the managers of this organization and emphasized in different sectors, educational needs assessments with emphasis on job anchors and organizational commitment for greater efficiency and determination and development of continuous training programs for different parts of the organization. In this way, empowering employees, organizational efficiency is improved.

Acknowledgments

The cooperation and advice of the Deputy Minister of Research and Technology (Clinical Research Development Unit of Baqiyatallah Hospital) is appreciated and thanked. The ethics committee of Baqiyatallah University of Medical Sciences with the ethics code IR.BMSU.REC.1396.350 approved this study in 1996. In addition, the Research Council of Baqiyatallah University of Medical Sciences has approved this plan with the code 91001779.

Conflict of interest

The authors of this study state that there is not conflict of interest.

ORIGINAL ARTICLE

Introducing a new medical method innovative suture technique to reduce scars in central lip lift medical surgery

Seid R. Hosaini[1], **Kamyar Azhdari**[2]

Abstract: *The central lip lift surgery with a new suture technique called; continuous locking suture in three cases is reported in this article. In this novel method, we used a 5.0 chromic suture by applying a 30-degree angle of the entrance to the skin semi-deeply. We start suturing at the middle of the wound,3-4 mm from the edges of the skin. The needle should be way out at the exact point of entrance, and this process is repeated to reach out to the two sides of the wound. More than 90% of patients (in more than 100 cases) were satisfied with the cosmetic results. Moreover, 90% of cases did not demonstrate any scar after three months without laser or reconstructive ointments. We evaluate many patients who undergo central lip lift surgery with this novel technique, and the scar problem was resolved in more than 90 % of cases with no supportive treatment.*

Keywords: *scar, central lip lift surgery, cosmetic results, patients*

INTRODUCTION

The central lip lifts

The first doctor that performed central lip lift surgery was Dr. Austin in 1980 and presented 83 cases in 1986. The lip lift surgery is performed to make the long lip of aging shorter and is designed to excise the wavy ellipse skin that follows the contour of the nostril crease below the sill. However, the nostril sill is not degraded. No attempt is needed to hide the scar in the nose; the reason is that the scar is well-hidden in the fold and is usually undetectable [1-3].

The continuous locking suture is an innovative method in central lip lift surgery that can be applied for at least six possible goals in closing the wounds made by the scalpel and are full-thickness. These goals are as follows: 1) reduce tension in the dermis, 2) reduce scarring after the surgery, 3) reduce suture marks to get an excellent cosmetic result, 4) Reduce the wound healing process to 5-6 days, 5) It is not visible in the surface of the skin. However, none of the other suture techniques fulfills all five above criteria. Those techniques that achieve good epidermal wound apposition will not give dermal support, may cause suture marks, or require wound care such as laser or medications. Those techniques that reduce tension in the dermis will not lead to precise epidermal wound edge apposition. The locking suture is a continuous suture. Three cases are presented in which the continuous locking suture was used in central lip lift surgery. The details of this technique are reported in this article. Finally, the advantages of the continuous locking intradermal suture will be summarized.

CASE SERIES

Case 1

A 40-year-old man clinically had a long distance between his nose and mouth (Figure 1). The area was disinfected with chlorhexidine and draped in the usual manner at the surgery. The lower incision is applied first via a 15-blade scalpel to the skin perpendicularly, reaching out to the fat and muscle junction. After that, the upper incision is made parallel to the lower incision; after finishing the surgery, suspension and closure must be performed accurately. In our novel technique, we start from the middle of the wound, insert the needle via a 30-degree angle for about 3-4 mm to the upper edge of the wound, and then take out the needle at the exact

[1] Ahvaz Jundishapur University, Iran
[2] Department of plastic surgery, AJA University of medical sciences, Imam Reza hospital, Tehran, Iran

Corresponding author: Kamyar Azhdari
Kamyar.azhdari60971@gmail.com

entrance point. Then, we perform the exact procedure on the lower edge of the wound and continue the process by the end of the incision. The wound was lastly dressed with transparent dressing and Bacitracin ointment. The patient came back for a follow-up examination in 30 days (Figure 2). At the first postoperative examination, no obvious scar was detected, and the patient was fully satisfied.

Figure 1: The 40-year-old man before the surgery

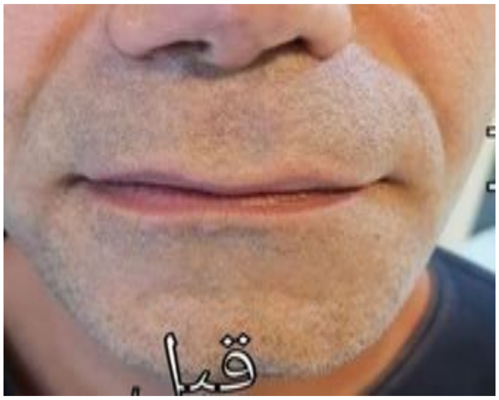

Figure 2: The 40-year-old man 30 days after the surgery

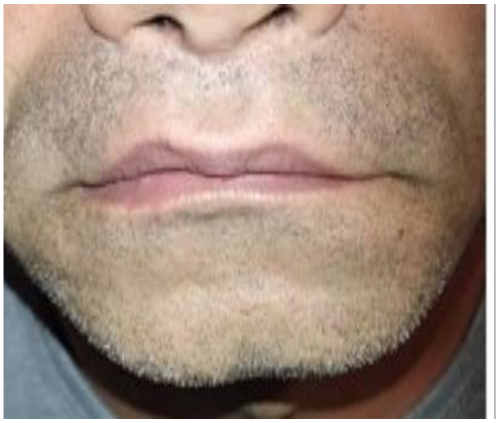

Case 2

Second case was a 40-year-old white woman. At central lip lift surgery, the goal area was cleansed by chlorhexidine. A superficial, vertical incision was made, and the skin and the subcutaneous flap were then excised over the orbicularis, remaining a thin glossy layer of fat intact. The edges of the skin were undermined to reduce the tension. Finally, The wound was closed via a continuous locking suture using 5-0 Vicryl (Figure 3). Bacitracin ointment was administered to the surgical wound. At the follow-up visit 30 days later, the wound edges were fully approximated. No redness or irritation was detected at the surgical site, and the wound was healed completely (Figure 4).

Figure 3: The 40-year-old woman before the surgery

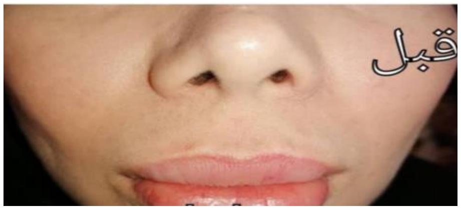

Figure 4: The 40-year-old woman 30 days after the surgery

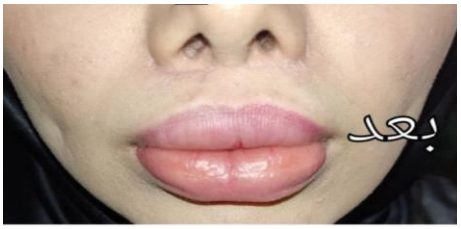

Case 3

A 20-year-old woman underwent central lip lift surgery, the area of the incision was cleaned with chlorhexidine. A superficial, vertical incision was made by the scalpel. The edges of the wound were undermined to decrease the tension. In the end, the wound was closed with 5-0 Vicryl with a continuous locked suture (Figure 5). Bacitracin ointment was administered to the surgical wound. At the patient's first postoperative visit, the wound was closed five days later without any scar. The wound edges were greatly approximated. A follow-up examination at one year demonstrated that the wound healed completely (Figure 6).

Figure 5: The 20-year-old woman before the surgery

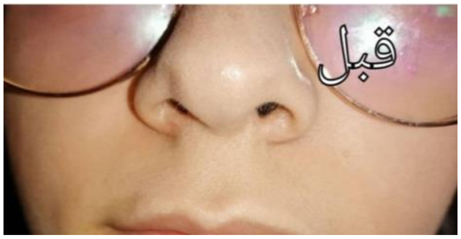

Figure 6: The 20-year-old woman after the surgery

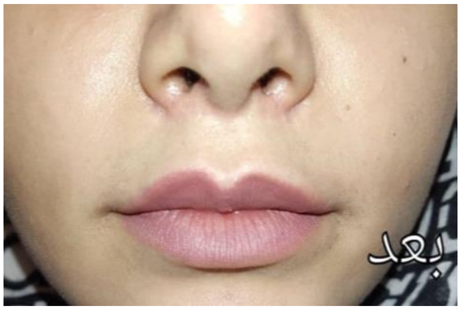

THE CONTINUOUS LOCKING SUTURE

Excision

The procedure is done using local anesthesia, and there is a surgeon at the head of the bed. The lower incision is performed first via a scalpel (15 blades) perpendicular to the skin, reaching out to the junction of the fat and the muscle. The upper incision is made parallel to the lower one in the next step. There is a thin glossy layer of fat which is left after excision of the skin and subcutaneous flap. This intact glossy layer is where vasculature lays, which is deep to the superficial muscular aponeurotic system (SMAS).

Dissection

After the excision process, we elevate the labial flap in a deep sub-SMAS plane. This dissection makes the labial SMAS free from the underlying orbicularis oris. The area of dissection is at the surgeon's discretion, as a larger dissection area may mitigate tension; however, it causes a considerable increase in postoperative swelling. The effacement of the Cupid's bow is probable in full central dissection. In most patients, the dissection extends to the vermillion, lateral to the philtral columns, and just finished before the nasolabial fold.

Suspension and Closure

Simple dermal closure is performed by most practitioners, which is the prevalent mistake [4]. The best lift can be obtained by doing an adequate release of tethering and then suspense the dense tissue upward in a fixed area. When this is done in the upper lip, the skin/SMAS flap released can roll over above the contracted orbicularis.

The continuous locking suture technique

In our novel technique, we start from the middle of the wound, insert the needle via a 30-degree angle for about 3-4 mm to the upper edge of the wound, and then take out the needle at the exact entrance point. Then, we perform the exact procedure on the lower edge of the wound and continue the process by the end of the incision. This technique is called locking because the 30 degrees of entrance and back and force repeatition, let the suture be locked in the skin. This provides a great advantage to push the dermal edges together. In the end, the incision must be closed from the center to the lateral. Then, the skin edges are closely approximated. At the lateral most side, a 4-0 Vicryl suture is passed from inside the pyriform, emerging radially to obtain the SMAS and then come back into the nose to complete a mattress suture. It is better to identify and protect the inferior alar artery.

RESULTS AND DISCUSSION

More than 100 cases had great cosmetic results with very few consequences. In 3 patients which were reported, any slight inflammation resolved within a few days of the first follow-up visit. None of the cases experienced significant discomfort or wound infection. The continuous locking suture combines beneficial features of other common techniques. It is locked for reducing any tendency to loosen. As a result, the apposition of wound edges is better.

CONCLUSION

There are five benefits for continuous locking suture: 1) reduce tension in the dermis, 2) reduce scar after the surgery(more than 90 % of patients did not demonstrate any scar after surgery without laser or other medication), 3)this technique is so effective in central lip lift surgery, 4) Reduce the wound healing process to 5-6 days, 5) It is not visible in the surface of the skin. In this technique, if the applied pressure to the needle increases, it can reduce the area's blood supply when the needle is excised from the nose. This reduction of blood supply can lead to small necrosis. All in all, we should regulate the applied pressure to prevent necrosis in the affected area.

Medical and chemical efficacy of respiratory physiotherapy and Remdesivir in patients with COVID-19 pneumonia: A systematic review and meta-analysis

Alireza Bahmani[1], Zahra Mollashahi[2], Negar Shahkarami[3], Elahe Delavar[4], Hooman Esfahani[5]

Abstract: *Evaluated efficacy of Respiratory Physiotherapy and Remdesivir on patients with COVID-19 pneumonia. In current systematic review and meta-analysis study, articles published January 2019 to December 1, 2021 were reviewed in the databases of PubMed, Scopus, Web of Science, and EBSCO. Risk ratio and mean differences with 95% confidence interval (CI), fixed effect model and Mantel–Haenszel or Inverse-variance formula were calculated. The Meta analysis have been evaluated with the statistical software Stata/MP v.16 (The fastest version of Stata). Mean differences of PaO2/FiO2 ratio at 6h after chest Respiratory Physiotherapy was (MD, 66 mmHg 95 % CI 64.71 mmHg, 67.28 mmHg; p=0.0007). Risk ratio of recovery rate between experimental and control group was 0.20 (RR, 0.20 95 % CI 0.15, 0.25) with high heterogeneity (I2 =78.84%; p=0.00). Risk ratio of mortality rate between experimental and control group was -0.34 (RR, -0.34 95 % CI -0.65, -0.03) with low heterogeneity (I2<0%; p=0.51). Based on the findings of meta-analysis, Respiratory Physiotherapy can play an effective role in respiratory therapy and rehabilitation of patients admitted to the ICU with COVID-19. A meta-analysis showed that treatment with Remdesivir could increase the recovery rate, especially in the early days of COVID-19; also reduces the mortality rate.*

Keywords: *COVID-19, respiratory physiotherapy, Remdesivir*

INTRODUCTION

Coronaviruses are a large family of viruses. From this collection, seven species transmitted to humans have been discovered so far, which cause diseases such as colds in humans [1]. Coronaviruses often attack the respiratory tract and sometimes show symptoms in the intestines and stomach [2,3]. Coronaviruses usually first infect the mucous membranes of the respiratory tract in the throat and nose, causing symptoms similar to the common cold [4]. Coronaviruses usually first infect the mucous membranes of the respiratory tract in the throat and nose, causing symptoms similar to the common cold [5]. Sometimes can cause more serious illnesses such as bronchitis and exacerbation of asthma and chronic bronchitis in adults and even lung infection (pneumonia) in adults, the elderly and people with weakened immune systems [6]. Covid-19 is an airway infection caused by a mutated version of the coronavirus and was first reported in Wuhan, China in December 2019 [7]. Initially, the mortality rate of patients with Covid-19 was announced at 3 to 5 percent, but recent reports have shown a reduction in mortality [8]. Due to the fact that this disease is very new and emerging, so scientific and documented findings in this area are very few. Therefore, considering the secondary effects that this disease has on the pulmonary system and affects the pulmonary system, so specialized findings on the improvement of pulmonary patients and their conclusion are very helpful in advancing the goals [9]. Physiotherapists, as a member of the multiple treatment team in the intensive care unit, play an effective role in reducing respiratory complications and preventing weakness due to hospitalization in the intensive care unit [10]. Since one of the most important organs involved in Covid-19 disease is

the respiratory system.

Therefore, the role of physiotherapists, especially in the field of respiratory physiotherapy, along with other health professionals, plays an important role in the treatment and care of this group of patients and overcoming the respiratory symptoms of patients with Covid-19.

In addition to medical treatment, rehabilitation techniques and pulmonary physiotherapy are essential for the treatment and improvement of patients' respiratory function. These measures are also recommended as self-care training and breathing exercises for quarantine patients at home [11]. Pulmonary rehabilitation has a variety of techniques, including breathing exercises and chest physiotherapy that help clear the airways, create a deep breathing pattern, increase arterial oxygen saturation and improve pulmonary volume, and increase voluntary expiratory volume in the first second [12]. Due to the increase in hospitalization costs, reducing the risk of nosocomial infections, reducing the number of hospitalizations, pulmonary rehabilitation programs for empowerment and also improving patients' self-care have been emphasized more than before; Therefore, the main role of physiotherapists to start patients' pulmonary rehabilitation programs at the time of hospitalization and the emphasis on continuing and following it at home becomes more apparent. Therefore, the aim of current study was evaluated efficacy of Respiratory Physiotherapy and Remdesivir on patients with COVID-19 pneumonia.

METHOD

In this systematic review study, Science direct, Google scholar, PubMed, Scopus, Web of Science, and EBSCO databases were used to search for articles. The present study is a systematic review and meta-analysis. In current study review of previous studies, the Preferred Reporting Items for Systematic Reviews (PRISMA) checklist was used to search for the studies [13].

Figure 1: Flowchart of the literature search and selection criteria

Respiratory Physiotherapy (n=1)
Remdesivir (n=3)

Data Extraction and analysis method

The data were extracted from the research included years, study design, number of patients, mean of age. To extract the data, two blind and independent reviewers extracted the data from the abstract and full text of the studies. Prior to screening, kappa statistics were performed to confirm the level of agreement between the reviewers. Kappa values were higher than 0.80.

Risk ratio and odds ratio with 95% confidence interval (CI), fixed effect model and Mantel–Haenszel formula; mean differences with 95% CI, fixed effect model and Inverse-variance formula were calculated. Random effects were used to deal with potential heterogeneity and I2 showed heterogeneity. I2 values above 50% signified moderate-to-high heterogeneity. The Meta analysis have been evaluated with the statistical software Stata/MP v.16.

RESULT

Respiratory physiotherapy: A total of 5 articles were found in the initial search. After removing duplicates, entry criteria for the titles were applied to the remaining 5 articles, and a summary of the remaining articles was reviewed. In this step, 4 articles were excluded. In the next, full text of 1 article were reviewed, finally one study was selected.

Remdesivir: A total of 89 articles were found in the initial search. After removing duplicates, entry criteria for the titles were applied to the remaining 69 articles, and a summary of the remaining articles was reviewed. In this step, 53 articles were excluded. In the next, full text of 16 articles were reviewed and 13 articles were excluded, finally three studies were selected.

Characteristics the studies included for evaluated efficacy of respiratory physiotherapy

One study (observational study) has been included in present article. The number of patients a total was 20 with mean age 63 years. Table 1 showed summary of studies for patient demographics, comorbidities, and clinical manifestations. Only one studies was found that evaluate efficacy of respiratory physiotherapy in COVID-19 patients [14].

Table 1: Summary of characteristics of included studies

Study. Years	Study design	Number of patients	Mean of age	Type of ventilation during RPT	ICU discharge characteristics
Battaglini et al., 2021 [14]	observational study	20	63	45% PSV 55% COT	% 5 Dead 95% Alive

PaO_2/FiO_2 ratio

Battaglini et al., 2021 [14] reported that PaO2/FiO2 ratio improved at T1 (RPT) compared to T0 (baseline) (MD, 63 mmHg 95 % CI 61.83 mmHg, 64.16 mmHg; p=0.00), the mean differences of PaO_2/FiO_2 ratio at 6h after chest RPT was (MD, 66 mmHg 95 % CI 64.71 mmHg, 67.28 mmHg; p=0.0007), this result showed PaO_2/FiO_2 ratio improved at 6h after chest RPT than baseline (Table 2).

Lung ultrasound score (LUS)

According to Battaglini et al.,2021 [14] study, the mean difference of LUS score between baseline and immediately after RPT was (MD, -4.95 % CI -4.26, -3.75; p=0.00).

Battaglini et al., 2021 [14] reported Correlation between LUS and CT scan, volume of gas and hyperaeration at CT scan between baseline, immediately after RPT and 6h after chest RPT, the result showed there was statistically significant association between LUS score and lung gas volume.

Characteristics the studies included for evaluated efficacy of Remdesivir

Three studies have been included in present article. The number of patients in experimental and control group was 1,125 with mean age 60.55 years and 799 with mean age 60 years, respectively. In all studies used 200 mg loading dose (IV), 100 mg maintenance dose from Second to Tenth day. The follow up period in two studies was 28 days and in one study was 29 days (Table 3).

Table 2: Meta-analysis of PaO_2/FiO_2 ratio

Group	Study	Mean Diff.	[95% Conf. Interval]		% Weight
Baseline – Immediately after RPT	Battaglini et al., 2021 [14]	63.000	61.838	64.162	54.92
Baseline – 6h after chest RPT	Battaglini et al., 2021 [14]	66.000	64.717	67.283	45.08

Meta-analysis summary Fixed-effects model Method: Inverse-variance Test of theta = 0: z = 146.42 Test of homogeneity: Q = chi2(1) = 11.54	Number of studies = 2 Heterogeneity: I^2 (%) = 91.33 H^2 = 11.54 Prob > |z| = 0.0000 Prob > Q = 0.0007

Figure 2: The Forest plot showed mean differences of lung ultrasound score

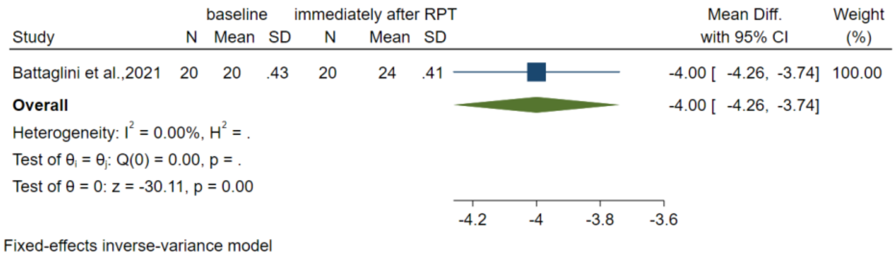

Table 3: Summary of characteristics of included studies

Study. Years	Number of patients		Mean of age		Remdesivir arm	Follow up period (day)
	Treatment	Control	Treatment	Control		
Spinner et al., 2002 [15]	384	200	58	57	200 mg loading dose (IV), 100 mg maintenance dose/2, 5 and 10 days	28
Wang et al., 2020 [16]	158	78	66	64	200 mg loading dose (IV), 100 mg maintenance dose/2-10 days	28
Beigel et al., 2020 [17]	583	521	58	59	200 mg loading dose (IV), 100 mg maintenance dose/2-10 days	29

Recovery rate

Risk ratio of recovery rate between experimental and control group was 0.20 (RR, 0.20 95 % CI 0.15, 0.25) with high heterogeneity (I2 =78.84%; p=0.00) (Figure 3). Subgroup meta-analysis showed Risk ratio of recovery rate on 7th day between experimental and control group was 0.19 (RR, 0.19 95 % CI 0.06, 0.33) with moderate heterogeneity (I2 =52.24%; p=0.12) (Figure 3).

Risk ratio of recovery rate on 14th day between experimental and control group was 0.29 (RR, 0.29 95 % CI 0.20, 0.38) with high heterogeneity (I2 =90.51%; p=0.00); Risk ratio of recovery rate on 28th day between experimental and control group was 0.13 (RR, 0.13 95 % CI 0.06, 0.20) with low heterogeneity (I2 =49.21%; p=0.14).

Remdesivir treatment significantly increased the recovery rate.

Mortality rate

Risk ratio of mortality rate between experimental and control group was -0.34 (RR, -0.34 95 % CI -0.65, -0.03) with low heterogeneity (I2<0%; p=0.51) (Figure 4).

Subgroup meta-analysis showed Risk ratio of mortality rate on 14th day between experimental and control group was -0.44 (RR, -0.44 95 % CI -0.82, -0.10) with low heterogeneity (I2<0%; p=0.52); Risk ratio of Mortality rate on 28th day between experimental and control group was 0.04 (RR, 0.04 95 % CI -0.59, 0.67) with low heterogeneity (I2<0%; p=0.67); Remdesivir treatment significantly reduction the mortality rate.

Adverse effects

Risk difference of adverse effects between experimental and control group was -0.01 (RD, -0.01 95 % CI -0.02, -0.00) with low heterogeneity (I2=27.92%; p=0.17) (Figure5).

Subgroup meta-analysis

Increased serum alanine aminotransferase

Risk difference of Serum alanine aminotransferase between experimental and control group was -0.01 (RD, -0.01 95 % CI -0.02, -0.00) with high heterogeneity (I2=79.26%; p=0.01).

Increased aspartate aminotransferase

Risk difference of aspartate aminotransferase between experimental and control group was -0.02 (RD, -0.02 95 % CI -0.03, -0.00) with low heterogeneity (I2=34.50%; p=0.22).

Increased bilirubin

Risk difference of bilirubin between experimental and control group was -0.00 (RD, -0.00 95 % CI 0.01, -0.01) with low heterogeneity (I2<0%; p=0.96).

Decreased creatinine clearance

Risk difference of Creatinine clearance between experimental and control group was -0.01 (RD, -0.01 95 % CI -0.02, 0.01) with low heterogeneity (I2=33.40%; p=0.20).

Vomiting

Risk difference of Vomiting between experimental and control group was 0.02 (RD, 0.02 95 % CI -0.02, 0.07) with low heterogeneity (I2<0%; p=0.33).

Figure 3: The Forest plot showed recovery rate on 7, 14 and 28 days

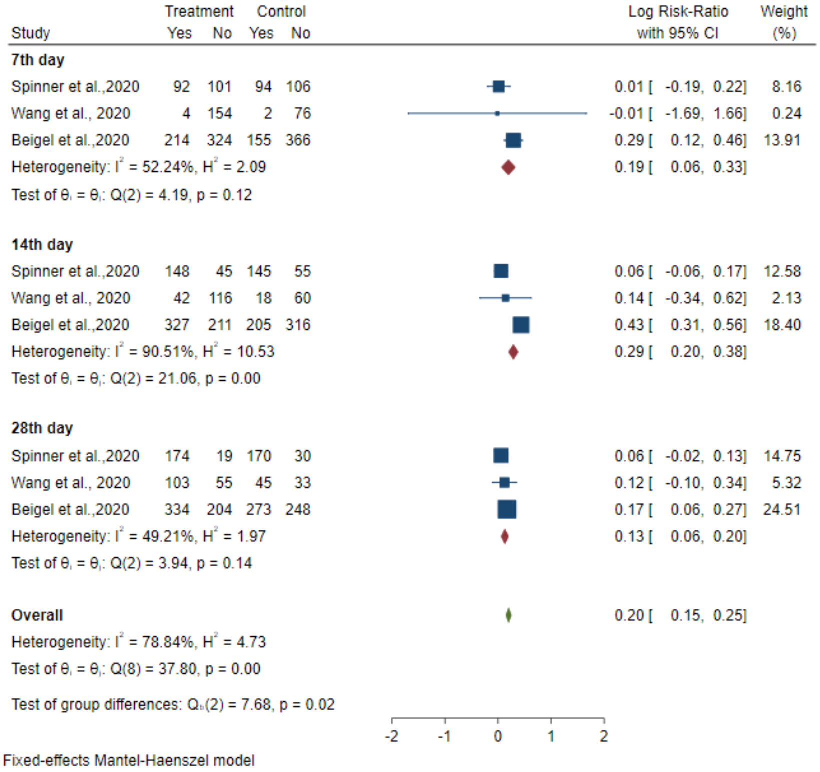

Figure 4: The Forest plot showed mortality rate on 14 and 28 days

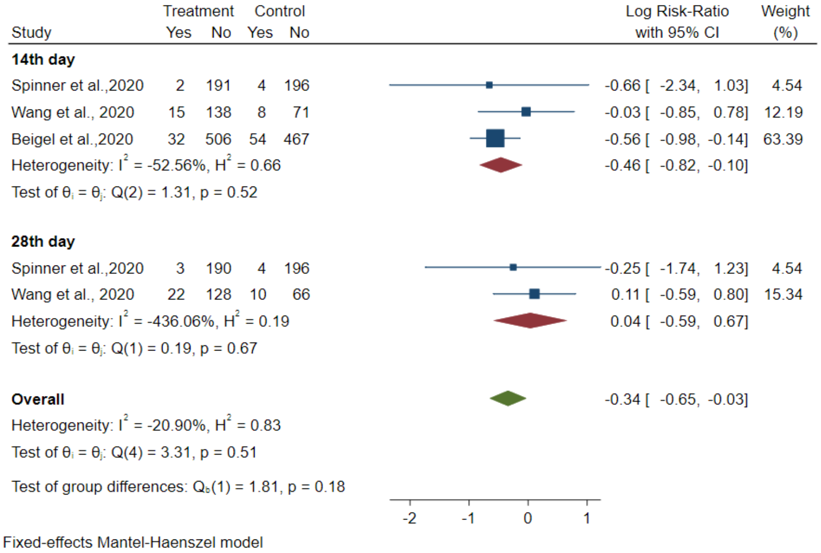


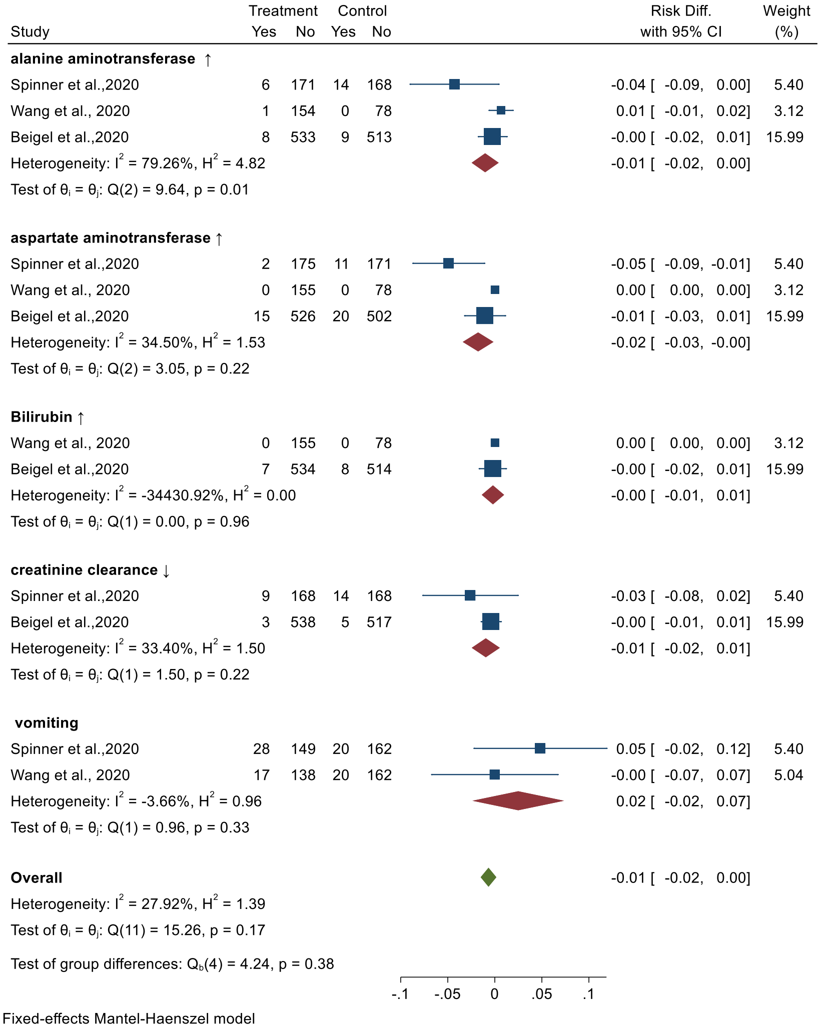
DISCUSSION

The aim of current systematic review and meta-analysis study was evaluating the efficacy of Respiratory Physiotherapy and Remdesivir on patients with COVID-19 pneumonia.

Meta-analysis showed respiratory physiotherapy improves oxygenation in critically ill COVID-19 patients. Only one study [14] was found to investigate the role of respiratory physiotherapy in patients with COVID-19. Hence, further studies are needed to emphasize the findings.

However, the findings showed that respiratory physiotherapy plays an important role in the rehabilitation of patients admitted to the ICU [18].

Figure 5: The Forest plot showed adverse effects



A study did not find a role for respiratory physiotherapy in patients with different respiratory patterns. As the meta-analysis shows, the LUS score improved, but these findings were not statistically significant. LUS is a diagnostic tool in the prognosis of COVID-19 [19]. To confirm this evidence, studies with larger sample sizes are needed to investigate the role of respiratory physiotherapy in patients with COVID-19 [14]. Limitations of the present study on the role of respiratory physiotherapy are: the existence of only one study, small sample size, and observational study (retrospective), RCT studies were not found, the study was conducted at the peak of COVID-19 epidemic, no comparison was found with the control group to evaluate the effectiveness of respiratory physiotherapy. Therefore, summarizing the practical and effective techniques of pulmonary physiotherapy is valuable to increase the awareness of all audiences, including physiotherapists, nurses and patient caregivers. Most review studies indicate that pulmonary physiotherapy is a safe and effective intervention, especially in stable conditions, to clear the lungs and improve the patient's respiratory function. Of course, there are a number of precautions and time limits for performing these techniques that should be considered. According to the Guideline published in March 2020 for physiotherapists in the treatment of patients with COVID-19, cardiopulmonary physiotherapy focuses on the treatment and rehabilitation of acute and chronic respiratory conditions in patients and aims to improve the physical fitness of individuals seeking the disease. Accordingly, physiotherapy can play an effective role in respiratory therapy and physical rehabilitation of patients with COVID-19.

To evaluated effectiveness of remdesivir, only three studies were found to be included in the meta-analysis. In these studies, the role of remdesivir on days 7, 14 and 28 in patients with COVID-19 was investigated. Meta-analysis showed that the effectiveness of remdesivir in these patients increases the recovery rate and reduces the mortality rate. Studies show that Remdesivir is more effective on the seventh day in the early stages of the disease, and patients who do not require mechanical ventilation respond better to Remdesivir [20]. According to the guidelines of the national institute of health, remdesivir works best in hospitalized patients with COVID-19 who require less supplemental oxygen [21]. However, further studies are needed to confirm these findings and provide sufficient and stronger evidence, as there is insufficient evidence to confirm the effectiveness of remdesivir in mild to moderate patients, and further studies are needed. Meta-analysis showed that the mortality rate on the 14th day of hospitalization was lower than on the 28th day, further studies are needed to confirm these findings [15,22].

The findings of this study are consistent with the results of previous meta-analysis studies [23,24]. However, the experimental studies reviewed in the current and previous meta-analysis were very few and, in most studies, the same, more RCT studies are needed in this area. Limitations of the study on the effectiveness of remdesivir in the treatment of patients with COVID-19 include: High heterogeneity in study results, time difference between results, age difference of patients, and low number of studies, low sample size and risk of bias not evaluated.

CONCLUSIONS

Meta-analysis showed that respiratory physiotherapy improves oxygen delivery in ICU patients with COVID-19, especially in less severe patients. It is recommended to review various respiratory physiotherapy techniques and their effectiveness in future studies. All respiratory physiotherapy interventions should be carefully considered to reach a complete conclusion in this regard. Unfortunately, so far only one study has been performed to evaluate the effectiveness of respiratory physiotherapy as a retrospective observational study (without control group); RCT and intervention studies are needed to confirm the effectiveness of respiratory physiotherapy techniques in patients with COVID-19. Based on the findings of meta-analysis, respiratory physiotherapy can play an effective role in respiratory therapy and rehabilitation of patients admitted to the ICU with COVID-19.

In the present study, a meta-analysis showed that treatment with Remdesivir could increase the recovery rate, especially in the early days of COVID-19; also reduces the mortality rate, although there is insufficient evidence in this regard because high heterogeneity was found between studies, so the reduction in mortality has not been proven. The efficacy of Remdesivir in patients with severe COVID-19 who do not require mechanical ventilation has been clearly demonstrated.

ORIGINAL ARTICLE

Medicinal plants effective in the treatment of glaucoma from the perspective of traditional Persian medicine

Ebrahim Heida[1], Assie Jokar[2,3], Omid Sadeghpour[4], Ebrahim Nasiri[3,5], Kiumars Nowroozpoordailami[6]

Abstract: *Traditional Persian medicine (TPM) is one of the richest medical schools in the world, which has nurtured valuable books. From Ibn Sina's law to Heravi's successful medicinal facts, all emphasize the treatment of various diseases, especially eye diseases based on herbal medicines, as well as their prevention. In this study, by reviewing the authoritative books of Traditional Persian Medicine, we are looking for medicinal plants so that they can be used in the treatment of glaucoma or glaucoma. the purpose of this study is not to express the complete cure of glaucoma, but this article seeks to classify plants that from the perspective of Traditional Persian Medicine can be used as complementary medicine alongside conventional medical treatments.*

Methods and Materials: This is a summative qualitative content analysis that focused on Traditional Persian Medicine (TPM) texts from 2th to 13th AH centuries. Literature was searched during centuries 4th to 13th AH, and after described of glaucoma, extracting and classifying plants.

Results: The scholars of TPM have opinions in the field of recognizing, describing and treating eye diseases and defining practical words. In almost all books of general Persian PM, the diagnosis and treatment of eye diseases have been discussed. Glaucoma in Traditional Persian Medicine is called "black water".

Conclusion: Unlike other medical schools in the world, in addition to treating diseases, Persian medicine has a strong recommendation to prevent the occurrence of disease and also to strengthen the body's visual powers by using 6 principles of maintaining health along with herbal medicines.

Keywords: *traditional medicine, traditional Persian medicine, glaucoma, classify plants*

INTRODUCTION

The discovery of drugs in the modern era began in the nineteenth century with the separation of active compounds from plants, such as morphine, from opium [1]. Initial treatment for glaucoma relied on herbal remedies, but the method of preparation of these drugs was raw and experimental [2]. One of the first herbs used for glaucoma was pilocarpine - a parasympathetic alkaloid extracted from a South American shrub, Pilocarpusmicrophyllus [3]. Pilocarpine causes the ciliary muscles to contract, which facilitates the outflow of fluid from the trabecular meshwork into the iridocorneal angle of the eye [4]. Although pilocarpine is still available for glaucoma management, its use has declined due to the availability of modern anti-glaucoma drugs with safe side effect profiles [5]. Glaucoma is a major cause of irreversible vision disorders and blindness worldwide [6]. The current standard of glaucoma care is intraocular pressure (IOP) reduction through medical, laser, or surgical treatment [7]. However, the use of alternative

therapies such as herbs, vitamins and minerals has become more common. Alternative therapies (methods other than conventional medical therapies) have a global market of $ 109 billion and are widely used by 52% of the general population [8,9].

In the authorities of Traditional Persian Medicine, visual impairment has been considered as "impairment of vision" and it has been defined as any impairment in the practice of seeing. In this disease, even with effort, objects can not be seen as they are and in practice, error occurs [10]. The approach of Traditional Persian Medicine in the treatment of eye diseases such as glaucoma is to protect health based on lifestyle modification and emphasizes the importance of prevention. In the field of modern therapy, although drug therapy and other invasive therapies are used to treat patients, but lifestyle modification, especially the emphasis on nutrition, has broadened the horizons of researchers in a variety of diseases, including eye diseases [11,12]. Ancient Persian physicians specialized in the diagnosis, description, and treatment of eye diseases, as well as in the definition of practical terms. Almost all books of Traditional Persian Medicine have diagnosed and treated eye diseases. In addition, several specialized ophthalmology books have been written from the perspective Traditional Persian Medicine [13]. About 25% of all medicines prescribed are made from herbs. Medicinal plants are less known for their low toxicity, effectiveness and side effects. A wide range of herbs have been found to be effective in treating eye diseases such as cataracts and glaucoma in complementary medicine schools, such as Ayurveda and Chinese medicine [14]. Studies have shown that the probability of discovering a new effective drug using traditional medical experiments increases by up to 40% versus random examination of drugs experimentally.

Therefore, searching for traditional reference books may be an effective way to find new drugs [15]. The purpose of this study is to provide a classified list of medicinal plants mentioned in Persian traditional medicine sources that after clinical studies can be used to enhance vision or treat poor vision.

It is worth noting that the vast majority of herbs in this study have not been used in clinical trial studies, so readers should refrain from any arbitrary use of these compounds if they do not have access to a competent physician.

METHODS AND MATERIALS

This research is based on the medicinal plants mentioned in the books Traditional Persian Medicine that somehow affect the improvement of visual function. As described, the purpose of this study is not to express the complete cure of glaucoma, but this article seeks to classify plants that from the perspective of Persian Traditional Persian Medicine can be used as complementary medicine alongside conventional medical treatments. Thus, from the books of the truths of medicine, the gift of the believers (Momen Tonekaboni), was used. The keywords "Ein", "Basar", "Basra" and "Magnifying" were used to evaluate the plants effective in increasing visual acuity and glaucoma. In such a way that any plant that has more than one of the above keywords, was selected as a plant that affects the visual status and increase the power of vision. The results of the studies can be seen briefly in Table 1.

Methods

This article is a summative qualitative content analysis that processed in seven classic steps:

The research questions to be answered: “What is glaucoma in the Persian medicine texts, we don’t find any disease that called as “Glaucoma”; To find the name of “glaucoma” disease in the context of Persian medicine, we tried to collect all data’s about glaucoma in the context of up to date modern medical texts; This information includes etiology, symptoms, signs, risk factor and treatment of glaucoma. And then we tried to find one disease have most overlap with glaucoma. As a result, glaucoma in Persian Medicine texts is known as “Ab e siyah”or black water” [1].

1. Selecting the sample to be analyzed: In this study, all of available Persian Medicine books and texts. These texts included manuscripts (the book itself or its electronic file) in different centuries from 11 to 20 A.D. we studied and searched historical books are in Table 1.

In the second step, the databases were searched by using key words of “glaucoma’s etiology, prevention and treatment” in PubMed, PMC, Google Scholar and Scopus.

2. To identify explicit versus euphemistic terms: Word frequency counts for each identified term calculated with source, to contextualize the codes. Modern equivalent terms were identified.

3. Coding process: three titles: definition and Name (Nam e Bīmārī); ethology (Asbāb va ʿElal); And treatment (Darmān). According to Persian Medicine text, we coded and categorized all data under these titles. We tried to translate these finding from Arabic & Ancient Persian to modern medicine language [1].

4. Defining the categories: All data was classified in three categories: definition, etiology and treatment of “Ab e siyah” [1].

5. Trustworthiness: Credibility, conformability & dependability: Given the explanation of different stage of methods such as key words, codding process, and etc. Anyone who has the ability to read and understand Arabic & Ancient Persian language & texts, can derive similar results.

6. Analyzing the result [26,27]: According to summative qualitative content analysis and given the skill of the authors of this article, we tried to collect all data about the prevention and treatment of glaucoma and introduced several plants as one of complementary treatment for effective treatment for glaucoma.

Table 1: Historical books which are used

Author	Title of the Book	Date Written	Subject
Ibn Sina	Book of law		
Ibn Nafis Gharshi	al-Shamil fi al-Sinaatah al-Tabiyyah		
Ali Ibn Hussein Ansari Shirazi	The authority of badi'i		
Mohammad Hussein Khorasani	The reservoir of medicine		
Ḥakīm Muʾmin M.	Tuḥfat al Muʾminīn	17th century	Traditional Medicine and Pharmacology
Razī M/Rhazes/Rasis	Al Ḥāvī fi al Ṭibb	10th century	Medicine
ʾAhwāzī A./Haly Abbas	Complete book of the medical art (Kāmil al-Ṣināʿa al-Ṭibbīya or Royal Medicine)	10th century	Medicine
Bīrūnī M.	Al Ṣaydana	11th century	Pharmacology
Avicenna/Ibn Sīnā H	Canon on Medicine (Al Qānūn fi al Ṭibb)	11th century	Medicine
Ğurğānī SI.	Ḏaḫīra ḫārazmšāhīi & Al ʿAġrāḍ al-Ṭibbīya wa al mabāhiṯ al ʿAlāīya	12th century	Medicine
Ibn Bayṭār	Tafsīr-u Kitāb discoridus	13th century	Medicinal Herbs

RESULTS

The scholars of traditional medicine have opinions in the field of recognizing, describing and treating eye diseases and defining practical words. In almost all books of general Persian medicine, the diagnosis and treatment of eye diseases have been discussed. Glaucoma Traditional Persian Medicine is called black water. This disease occurs in the moisture of the testicles (clear fluid), the causes of which are not out of two cases; It is either in quantity or in quality of testicular moisture [16]. This disease, ie glaucoma, has not been given special attention in Persian medicine textbooks and has been treated more under the title of eye diseases, and some reports have been recorded from them. Identified a specific disease as glaucoma; However, according to the anatomy mentioned in Persian books and the study of eye diseases in Persian medicine sources, it seems that glaucoma may be one of the diseases of testicular moisture. In Akbari Medicine, in the discussion of eye diseases, Volume 1, in the topic of testicular moisture, there are topics that seem to be compatible with glaucoma. This moisture is considered similar to the whiteness of the testicles in terms of consistency, purity and color, and the benefit of this moisture in front of the glide (eye lens) is that the strong lights are gradually placed on the glide and because of this, the glide is irritated and constipated. Preserved [17]. One of the diseases of this moisture is considered to be its large volume and it continues that if it was a small increase due to the lack of transparency that makes the majority of the necessary components, it would fail to adapt the ghosts to Jalidiyah and the radius would reach the natural duct. The volume should be more than that, in which case, the insight shakes itself, imagining in front of itself that the sea is standing and in the state of full stomach and back sleep, weakness in insight prevails and also when hunger in the middle of the day is not so weak. The patient sees the unlikely things better than the near objects, and the mutation is that the soul becomes dirty due to the abundance of this moisture, and because they do not move farther, its concentration is softened and its consistency is not moderated. And effort) can not be seen; Because in Absar, the relative sensations of the soul do not move so much that its concentration becomes soft [17].

Remedy

The first purification of the body should be done in the kitchen of Sajj and then with the purification of Sarhabn[17]. The body and the nose [18,19]. In removing the blockage and reducing the moisture of the testicles, drugs containing patience and halilah are used in the sources of traditional medicine [16]. In general, the symptoms mentioned in the books of Persian medicine, testicular hyperhidrosis seems to be consistent with the symptoms of chronic glaucoma. Visual impairment in different forms that exists in chronic glaucoma, in the increase of testicular moisture, which is the moisture between the cornea and the lens, these symptoms are also present in Persian books.

Elliptical moisture

From the point of view of traditional medicine, aqueous humor is behind the iris and anterior arachnoid. Aqueous humor has several roles, which is to protect the lens, to protect it from both natural internal heat and heat from strong light coming from outside, and to be a barrier between the lens and the iris so that the two do not intersect [18,20-22].

A. Quantity of testicular moisture

It should be less or more and smaller or bigger, and whenever it is more or greater than the natural amount, it should be veiled between the moisture of the jelly and between the outside light. His sign is that hunger and austerity are beneficial, and in the heat, it is better for half a day, and in the morning and evening it is worse, and the heat is harmful, and whenever it is less or less, it is due to the deterioration of the testicles. Analysis is repelled and dryness prevails. His sign is that the blackness of the eyes becomes smaller and is worse when he is hungry and in the heat for half a day, and mathematics is harmful, and baths and more food are increasingly beneficial [18].

B: Quality of testicular moisture

What is in quality or is a plague in consistency or is in decline in Loon or plague in wetness and dryness and what is in consistency is such that some moderate consistency is a little thicker and God cannot see this cause as far as he is and What is close, as it should be, cannot be seen by the good, and some of the temperate textures turn a lot and become hard and thick, and this is of two kinds, or some of its components become hard, or all of it, and if all of it becomes hard, it thickens the vision. And his ruling is the ruling of water is the same, and if some of his components are concentrated, it will reduce vision [18].

Maintaining health (maintaining health) in the eyes

A study in the sources of Iranian Persian medicine shows that the sages believed that the prevalence of eye diseases in winter is lower than in other seasons. In summer, due to the frequency of ascents, and in Rabi, due to the flow of substances, and in the opponent, due to the corruption of substances, it is more, and it is difficult to diagnose eye diseases, whether it is in the layers or moisture of the eyes, or in the nerves or partners. The temperament of the eye is a function of the temperament of the brain, on the other hand, because the eye has many arteries, most of it is temperate; because it requires a lot of movements and movements of the solution, and it is not necessary to make everyone's temperament hot. In traditional medicine for the treatment of eye diseases, the three principles of causal action, strengthening all the powers of the eye and purifying the eye from wastes have been mentioned as general rules. Eye diseases are some external, such as remedies, and some esoteric ones are easily defined, such as the state of the soul of Basra in its abundance and tenderness, and the like, and some esoteric ones are defined as pests that occur in moisture, and some esoteric ones are estimated, such as pests in the inner classes or The optic nerve is caused by mood swings and the like, eye diseases. Constipation and violence need to be corrected with violets and the addition of a little bit of sage. Iarj fiqra removes substances from the head if it is concentrated. The important point is that most eye diseases are caused by the organ of participation and it must be the members of the head, and most of this is when it occurs.

Harms of the eye

Lots of things may harm the eyes: dust and smoke, very hot and cold weather, wind, toxins, all kinds of things like too much sex, too much salt, long-sightedness towards shiny and bright things, excessive white like lightning and bright white, sun, snow, durability One thing, the setting of precise lines to extremes, too much incarceration, the frequency of crying, the intense sadness, the delusions and the rage, the study between evening and dusk, all the good news like garlic, beans, beans, onions, lentils, eggplant, mustard and blackberries, multiplicity strong laxatives, including abdominal astringents. But diarrhea is sometimes beneficial to drinking medicine and sometimes to congestion, and this is more beneficial in ingesting substances, and injections are beneficial to all material diseases of the eye, and the most agreeable laxatives in eye diseases are Halilah; Because it strengthens the stomach and prevents the excretion of substances, but due to the treatment of the eyes in a way before purification is not permissible [23]. In the book of Akbari medicine, he writes: The cure for eye diseases is of four genders, one is to change the simple temperament, the second is to purify the substance, the third is to manage the division of the joints, and the fourth is to correct the heat of the eye and reduce it. There are seven ways to make the eye vomit. Second, if the body is smooth, first clean the body from bad sputum. Thirdly, it is useful to clean the nose with meningeal sprays and to gather in the jugular vein of the veins that are inside the head. The use of sneezes has an effect on enemaing the eyes, but they should not cleanse the body until the substance is applied, which should not be done. It is harmful. The purity of the blood vessels of the eye is also conditioned by the priority of purification, so that the harm is safe and there is no harm where the body is clean. Among the drugs used in Persian medicine to empty the feces of the head, it seems that the drug of patience is a suitable drug to achieve the above goal. Other drugs include Halilah, which is frequently mentioned in the sources. Herbal medicine is the oldest form of treatment, known to mankind and has been used for a long time. The use of this method of treatment has a history in all civilizations and is an important component in the development of common medical science. The important point in all eye diseases mentioned in the sources is that the elimination of feces and its emptying and softening of nature are the general principles of treatment in the majority, and for this purpose, in most of the above cases, the love of patience and reason has been suggested.

Table 2: Plants identified from sources and references, in order from right to left, including Persian name, scientific name of the plant, method of consumption and references

Used reviews	How to use	Temperament	Scientific name of the plant	Persian name of the plant
[24-29]	Food	Warm and dry	Thymus capitatus	Thumon
[24-29]	It's my head.	Warm and dry	Peganumharmala L.	Espand
[24-29]	It's my head.	Warm and dry	Commiphoragileadensis	Arabic Bilal
[24-29]	Eye drops	Warm and dry	Marrubium vulgare L.	Mountain mess
[24,25, 27-29]	Food	Warm and dry	Rutagraveolens L.	Ruta graveolens
[24-29]	It's my head.	Warm and dry	Foeniculum vulgare L.	Foeniculum vulgare
[24-27, 29]	Food	Warm and dry	Allium cepa L.	Piyaaz
[25-29]	Food	Cold and dry	Terminalia bellerica	Belleric myrobalan
[26-29]	It's my head.	Warm and dry	Ferula assa-foetida L.	Ferula assa-foetida
[25-29]	It's my head.	Cold and dry	Solanum nigrum L.	Solanum nigrum
[24-29]	It's my head.	Warm and dry	Cinnamomumzeylanicum	Cinnamon
[25-29]	It's my head.	Cold and dry	Rheum ribes L	Rheum ribes
[25-29]	It's my head.	Warm and dry	Calotropisproceradryand	Calotropis procera
[24, 26-29]	It's my head.	Warm and dry	Aloe vera L	Aloe vera
[24-27]	It's my head.	Warm and dry	Zingiberofficinaleroscore	Zingiber officinale

As can be seen from the plants mentioned in Table 1, the vast majority of plants affecting the visual acuity and treatment of eye diseases had a dry temperament and most of them were hot and dry. Most of the plants are extracted from the medicine repository and the least of them are extracted from the medicinal plants and facts. It seems that according to the texts of medicine books, most plants were effective in strengthening vision and a few were effective in visual impairment. Meanwhile, most herbs have been shown to be effective in treating cataracts compared to other ocular disorders such as glaucoma. The method of consumption for most plants, like the common method of medicine for the treatment of eye diseases, is kohlrabi, but in the meantime, oral methods are also found to a lesser extent. Aqueous extract of fennel seed (Foeniculum vulgare) has protective and therapeutic properties against cataracts caused by sodium selenite in rabbit eyes. The possible mechanism of this extract is antioxidant activity. Various phytochemical studies have shown the presence of compounds such as flavonoids, phenolic compounds and volatile compounds in this plant. It has several other medicinal properties such as anti-inflammatory and anti-hypertensive effects. Lens opacity was lower in rabbits that received eye drops of aqueous extract of this plant twice a day for 5 days before cataract induction and 21 days after cataract induction [30]. Considering the antioxidant role of this drug in the treatment of cataracts, it seems that it can play a similar role in relieving the symptoms of glaucoma. In addition to its antioxidant properties, this plant also seems to be effective in reducing intraocular pressure. And can be used specifically to treat glaucoma. Another study by Agarwal et al. Showed that aqueous extract of fennel seed reduced intraocular pressure and its maximum pressure reduction was comparable to that of thymolol. The mechanism of action is through the effect of anti-cholinesterase, so its anti-glaucoma property is proven [31]. In the following clinical trial results, we will present several studies that prove the antioxidant properties of certain plants, since the herbal treatment of eye diseases such as glaucoma and cataracts is jointly based on its antioxidant properties, so the result can be It is likely that these drugs, which are effective against cataracts, will also improve eye conditions in glaucoma. Javadzadeh et al. Stated that administration of 1 drop of onion extract in the eyes of mice for 14 days every 8 hours prevents the formation of cataracts caused by selenite [32]. In 2010, a study by Gupta et al. On 9-day-old mouse puppies showed that intraperitoneal injection of aqueous extracts of Trifala (Emblica officinalis), Terminalia Bellerica and Terminaliachebula at 25 mg/d. Each kilogram of body weight prevents the formation of cataracts caused by selenite and the formation of selenite. In addition, the activity of antioxidant enzymes increases glutathione and reduces the amount of lipid peroxide in contrast to selenite-induced oxidative stress [33]. Another case-control study has shown the role of oxidative stress as the main mechanism of eye damage in cataracts, glaucoma and ARMD, which shows the role of plasma antioxidant capacity in the prevention of these eye diseases. Plasma antioxidant capacity is increased by foods rich in antioxidants such as fruits and vegetables [34]. Despite extensive research, there is insufficient clinical trial evidence of the effectiveness of all plants on visual impairment extracted from sources, but the antioxidant properties of many of these plants indicate their potency in treating or enhancing vision impairment. These include Aloe vera (Solanum nigrum) [35], Peganum Harmala [36], Zingiber officinalis [37], Ferula assafoetida [38], Rheum ribes [39] and Belila (Terminalia bellerica) [40].

DISCUSSION

Visual disturbances generally occur for a variety of reasons, including disorders of the interpretive part of the vision in the brain, disorders of the eyeball such as the layers of the eye (choroid, retina, and sclera), and eventually disorders of the optic nerves. In glaucoma or glaucoma, the disorder occurs due to increased pressure inside the eyeball for a variety of reasons, of which there are many types. Doctors of IranianPersian medicine attribute the causes of all diseases to not paying attention to the 6 principles of health (climatic and environmental conditions, food and drink, physical activity and rest, excretion status, mental condition and sleep and wakefulness). For this reason, they first try to treat the disease by regulating the above conditions, and then turn to the use of drugs and invasive measures such as surgery. In other words, Iranian Persian physicians believed that in the early stages of the disease, the disease can be controlled by maintaining and regulating the six principles of health, and only in advanced conditions of the disease should aggressive measures be taken. For example, in the treatment of cataracts (descent of water), Persian physicians initially sought to treat the disease with nutrition and herbs, and only in advanced conditions did they perform aggressive measures such as surgery. Also in glaucoma and cataracts, they advise not to eat meat, fish and fruits and also recommend to use dry foods [41]. Regarding the recommendation of medicine not to rush into initiating aggressive measures, Ibn Sina's law states that one should not rush to start cataract surgery and should wait until its sufficient progress [42]. In general, the opinion of Persian medicine in the field of eye diseases such as glaucoma is that some environmental conditions such as dust, very hot or very cold weather, smoke and looking at small objects too much to do too much Activities such as crying and sexual intercourse, eating too much salt, lentils, cabbage, garlic, sugar and alcohol eventually cause these diseases. On the other hand, it is highly recommended to eat foods such as saffron and turnips to improve eyesight [41]. The general mechanism of eye damage in diseases such as cataracts, glaucoma and age-related retinal detachment (ARMD), from the perspective of biochemistry, is oxidative stress. Oxidative stress leads to the formation of free radicals that can cause severe damage to the ocular and lens layers. Therefore, in the treatment and prevention of these diseases, the best way is to use antioxidants as complementary medicine. Table 1, which is mentioned in the results section, shows a group of plants with strong antioxidant properties, which seems to be the recommendation of Persian physicians to use these substances in the treatment of eye diseases [43]. Although some medical schools, such as traditional Chinese medicine, seek to treat glaucoma with the use of herbal medicines, it seems that the main recommendation of Persian medicine is to regulate the six conditions of maintaining health as well as the use of herbal medicines. In the form of kohl, drops and even oral, seeks to prevent the disease and increase the body's resistance to the disease. In fact, in the treatment of glaucoma, the herbal medicines mentioned in traditional medicine can be used as a complementary treatment to the main treatment, because in the acute stages of the disease, the use of invasive treatments such as surgery instead of herbal medicines, it seems inevitable.

CONCLUSIONS

Unlike other medical schools in the world, in addition to treating diseases, Persian medicine has a strong recommendation to prevent the occurrence of disease and also to strengthen the body's visual powers by using 6 principles of maintaining health along with herbal medicines. Finally, it is inferred from this study that despite the many benefits of using herbal medicines mentioned in Persian medicine books, but due to the lack of sufficient clinical evidence, until the effectiveness of these herbal medicines is proven, it is better to use them. Complementary therapy should be used alongside the main treatment (modern medicine). Despite the mention of numerous herbs for the treatment of eye diseases such as glaucoma and cataracts, as well as the strengthening of eyesight, but it seems because so far no proper clinical trials have been conducted in the field of trying these herbal medicines. This rich capacity of Persian medical experiences has been neglected. Therefore, it is recommended that Iranian Persian medical researchers in their future studies diligently test plant compounds using appropriate and valid research methods for the treatment of eye diseases.

New pathophysiological aspects in chronic venous disease

Nicuța Manolache[1], Gabriela Stoleriu[2], Daciana E. Brănişteanu[3], Silvia Robu[1], Camelia Diaconu[1], Daniel O. Costache[4]

Abstract: *Chronic venous disease has been pathology of great interest over time. With its large prevalence among the world population (10-33% adult woman and 10-20% of men) through profound socio-professional implications that affect the quality of life of patients, chronic venous disease is a real public health problem, being an important cause of morbidity and disability, a permanent area of research in the medical-pharmaceutical field. Special attention is now given to identifying the mechanisms and stages of disease development. From studies that have highlighted the importance of venous hypertension as an essential element in the development of the disease, to this day it has come up to demonstrating the fundamental role of the venous endothelium and glycocalyx in triggering and progressing of chronic venous disease. Biochemical, immunohistochemical, and functional investigations have allowed the evaluation of changes that occur in cellular metabolism and evidence of some immune-vascular factors responsible for vascular alterations in chronic venous disease: specialized receptors, adhesion molecules, cytokines, matrix and metalloproteinases.*

The analysis of the pathophysiology of chronic venous disease is still a vast area open to scientific research.

Keywords: *chronic venous disease, venous insufficiency, endothelium, glycocallix, matrix metalloproteinases*

INTRODUCTION

Chronic venous disease (CVD) is being defined as a long term decompensation of the venous circulation, with the occurrence of venectasia, reticular veins and hydrostatic varicose (secondary to venous stasis), stasis in the lymphatic system and various skin changes: vesperal or permanent edema, eczematous dermoepidermitis (stasis chronic eczema), pigmented purpuric dermatitis, dermohypodermitis with sclerous development (lipodermatosclerosis), Milian's white atrophy and leg chronic ulcer. [1]

The first information about CVD was suggested by prehistoric drawings and paintings, papyrus writings and hieroglyphic and cuneiform descriptions engraved in stone. Chronic venous hypertension (VH) and chronic venous insufficiency (CVI) may be secondary to venous pump failure due to the reflux of the varicosities of the superficial venous network or secondary to prior thrombosis of the veins (incompetence and/ or obstruction due to poor reperfusion of deep vein branches). Deep venous disease is associated thromboembolism. Rarely, CVI is due to primitive valvular insufficiency. VH will lead to permanent dilatation of the dermal veins visible through the epidermis. VH is responsible for capillary distention with extravasation of plasma, red blood cells, fibrinogen, α2-macroglobulin and other macromolecules, perivascular diapedesis of leukocytes, into the interstitium. Absorption capacity of the lymphatic vessels is exceeded resulting edema and chronic inflammatory changes. Edema compresses and deforms capillaries with microcirculation disorders. Fibrin deposits form sleeves around the capillaries that block nutritional changes. The slowing of blood flow in the capillaries favors the aggregation of the red blood cells. Small thrombus can obstruct the capillary lumen and leukocytes adhere to the vessel endothelium. The macromolecules trap growth and repair factors so that minor traumatic wounds cannot be

repaired and an ulcer develops. The activation of leukocytes release free radicals, proteolytic enzymes, cytokines (TNFα), leukotrienes, matrix and metalloproteinases responsible for capillary hyperpermeability and capillary and tissue injury.

ENDOTHELIUM AND GLYCOCALLIX

Endothelium is a key element in regulating vascular tonus, hemostasis and coagulation. Due to its structure the endothelial glycolalysis prevents leukocyte adhesion, inflammation and thrombosis. [2] Secondary to dilatation, increased blood flow and venous pressure, the endothelial function is negatively affected in CVI.

Through specific receptors the endothelium and the glycocallix detect the changes produced by the shear stress, with the stimulation of the chemoattractants (MCP-1, VCAM-1, ICAM-1) and nitric oxide activation, amplifying the inflammatory response with subsequent release of inflammatory mediators (chemokines, cytokines, growth factors and metalloproteinases), attraction of leukocytes (macrophages, monocytes, T lymphocytes) and their attachment and transmigration in venous and interstitial walls, inducing cutaneous modifications specific for CVI. [2,3] The changes in venous pressure and wall tension are perceived by the endothelial cells through ICAM-1 molecules (differentiation cluster 54-CD54-) that have an increased expression in patients with CVI. ICAM-1 molecules have a specific role in activation, adhesion of endothelial cells, leucocyte's diapedesis and transmigration and through transient receptor potential vanilloid channels (TRPVs). [4] They induce disruptions in the production of NO–, the release of vasoactive substances, the extravasation of macromolecules and erythrocytes that degrades in fibrin and hemosiderin with leucocyte activation, in the expression of MCP-1, MIP-1 and vascular cell adhesion molecule-1 (VCAM-1, CD-106) and in the expression and release of L-selectin and E-selectin. [5]

The adherence and transmigration of leukocytes in venous valves and venous walls triggers an inflammatory cascade, stimulating the production of tumor growth factor-β1 (TGF-β1) by the activated endothelial cells and smooth muscle cells [6] and the production of TNF-α and interleukin-1 (IL-1) factor with subsequent increased expression of matrix metalloproteinases (MMPs). [4,7,8]

VH determines the stretch of the venous wall and an increased venous wall tension, followed by an increased expression of hypoxia inducing factors (HIF-α1, HIF-α2) that further on induces an increase in the level of MMP-2 and MMP-9 in order to relax the venous wall, with the consequently development of the venous dilatations. [2]

THE ROLE OF MATRIX METALLOPROTEINASES, THEIR TISSUE INHIBITORS AND CYTOKINES

The mechanisms involved in the development of venous ulcer (VU) and the factors that intervene in the slowhealing process are not fully elucidated. The healing of chronic ulcers is a complex process involving inflammation, reepithelization, matrix deposits and tissue remodeling. These processes are controlled by MMPs and their tissue inhibitors (TIMP). In the case of VU, MMPs, zinc-binding endopeptidases, are synthesized by local proliferating fibroblasts, their activity being inversely proportional to the degree of healing. Generally, MMPs and TIMP are temporarily induced in response to exogenous signals, such as different proteases, cytokines or growth factors, cell-matrix interactions and modified cell contacts. Gelatinases MMP2 and MMP-9, as well as TIMP-1 appear to be elevated in exudates of VU compared to acute wounds. [6,9]

However, biopsy sample analyzes have shown variable results. MMP-1, MMP-2 and TIMP-1 levels were elevated in patients with lipodermatosclerosis compared to normal skin. [10] In a later investigation, biopsies from patients with VU were found to have elevated levels of active MMP-2 compared to normal skin.

MMPs production and their function is regulated by cytokines, urokinase plasminogen activator (uPa), extracellular matrix metalloproteinase inducer (EMMPRIN-CD147), AA platelet growth factor (PDGF-AA) and mitogen-activating protein kinases (MAPK). [11,12] Excessive MMP activity in the tissue is controlled by their endogenous inhibitors, tissue metabolic inhibitors (TIMP). In UV matrix metalloproteinase synthesis outweighs the effect of their tissue inhibitors, the imbalance resulting in the degradation of elastin and collagen. [13]

At the level of VU fibroblasts, MAPK pathways over-express p38, a negative modulator of cell proliferation, stopping the healing.

VH induces MMP activators which increase MMP expression and activity, extracellular matrix (ECM) degradation, relaxation of venous smooth muscle (VSM) and venous dilatation. [14,15] Inflammation of the venous wall causes additional increase in MMP levels, vein dilatation and valve dysfunction. [16] The result consists in remodeling and fibrosis of the venous wall causing progressive venous dilation and varicose vein formation. [14] The ECM composition is dependent on MMP and can affect the venous wall structure. In CVI there is an imbalance of the venous wall collagen types. The type III collagen responsible for tissue distension is low, whereas type I collagen – which determines rigidity – is high, leading to a reduction in the elasticity of the varicose veins. [16]

Imbalance between MMPs and TIMP activity increases MMP tisular levels resulting in degradation of elastin and collagen [13] with pathological changes of the venous wall and installation of CVI. Thus hypertrophic and atrophic vein segments develop in the varicose veins and damage the venous valves. The remodeling of the venous wall and abnormal venous distention restrains the valve's closure and therefore initiate the venous reflux. [6]

MMP-2 (gelatinase A) may induce venous relaxation or inhibition of venous contraction [17], affecting ECM remodeling in vascular structures and playing an important role in the development of the VU. Healing of VU is impaired in patients with high levels of MMP-2 and low levels of TIMP-2 in the ulcer's exudate. [16]

MMP-9 (gelatinase B) is considered to be the major protease in ECM degradation in chronic wounds. MMP-9 levels are much higher in cases of varicose veins and VU. [18] The MMP-2 and MMP-9 are up-regulated in experimentally induced VH, [19] and MMP-9 has been shown to influence remodeling of the vein by modulating the collagen content of the vein wall, thus contributing to inflammation and fibrosis. [16]

MMP-12 (macrophage metallomelastase) allows macrophage migration by degradation of several ECM components. MMP-12 can block angiogenesis, acting as a potent inhibitor of angiogenesis. MMP-12 concentration is increased in VU's exudate in the inflammatory phase compared to the granulation phase. [20]

In addition, MMP extracellular inducer (EMMPRIN) and membrane metalloproteinases type 1 and 2 (MT1-MMP and MT2-MMP) were detected in the dermal and perivascular regions of VU. [21] There are no differences in overall MMP-1, 2, 9 and TIMP-1 protein levels in patients with CEAP (Clinical, Etiology, Anatomical, Pathophysiology) class C2 to C6 CVD compared to normal controls. [6] However, in C6 CEAP class level, MMP-2 levels were increased compared to MMP-1, 9 and TIMP1 in patients with C4 and C5 CEAP class disease.

These data indicate that active tissue remodeling occurs in CVD patients. It is currently unclear which MMPs are involved and how are they activated and regulated. It appears that MMP-2 may be activated by uPa.

mRNA, uPa and urokinase plasminogen activator receptor have increased levels of in VU compared to normal skin. Elevated levels of active TGFβ-1 in the dermis of CVI patients suggest a regulatory role for TGFβ-1 in the synthesis and activity of MMP and TIMP. [6,22]

The regulatory role of TGFβ-1 in the synthesis and activity of MMP and TIMP is supposed by TGFβ-1 increased levels in the dermis of CVI patient as well as during the healing process of VU. TGFβ-1 is secreted by interstitial leukocytes and binds to dermal fibroblasts and ECM proteins, also increases with the severity of the CVD, being a risk factor. [23] The cytokines interfere with CVI pathophysiology in its various stages starting with inflammation. In the untreated VU there are elevated levels of pro-inflammatory cytokines (IL, TNF-α, IFN-γ).

Along with VH and inflammation, the cytokines interfere in post-capillary venules where they form asheath which includes collagen I and III, fibronectin, vitronectin, laminin, tenascin, fibrin, TGF-β1 and α2-macroglobulin. [7] Although the causes and mechanisms of fibrin sheath production are not fully elucidated, chemical and structural changes from dermal microcirculation will lead to the progressive installation of cutaneous trophic disorders and ulceration. [2,24- 26]

Red blood cell degradation products and interstitial protein extravasation are potent chemoattractants that represent the initial inflammatory signal at the base of responsibility for the recruitment of leukocytes. These cytochemical events are responsible for increasing intracellular adhesion molecule-1 (ICAM-1) expression on endothelial cells of microcirculatory vessels observed in dermal biopsies in patients with CVD.

ICAM-1 is the activation-dependent adhesion molecule used by macrophages, lymphocytes and mast cells for diapedesis. α and β platelet-derived growth factor receptors (PDGFR-α and PDGFR-β) and vascular endothelial growth factor (VEGF) have increased levels in CVD patients dermis. They are regulating upward adhesion molecules leading to leucocyte recruitment in CVD. [6]

CONCLUSIONS

Along with VH (key element), endothelium and glycocallix, MMPs and cytokines play an important role in the CVD pathophysiology. Understanding the physopathological mechanisms involved in triggering and evolving CVD, knowing the aetiological factors and the facilitating factors are an essential stage in the management of the disease, allowing the development of a complete therapeutic plan adapted to each patient.

Open treatment options in massive rotator cuff tears associated with acromion non-union

Cătălin S. Mitulescu[1,2], Radu Paraschiv[3], Sorin Lăzărescu[3], Mihai G. Avram[2], Stelian Lupaşcu[2]

Abstract: *We evaluated the available English literature for cases of acromion non-union and rotator cuff tear, looking at surgical methods of treatment as well as at functional results. As expected, the literature regarding rotator cuff pathology was found to be abundant, and a good number of articles were found regarding acromion non-union, but articles concerning the association of the two were scarce. Treatment recommendations varied, and were made on a case-to-case fashion. The accepted treatment methods for acromion non-union consist of non-surgical management, open or arthroscopic fragment removal, open or arthroscopic reduction and fixation (bone grafting may be used), while the rotator cuff witll be reinserted with anchors. In this rare occurence, a large rotator cuff tear with retracted tendons combined with an acromion non-union are usually repaired by an open technique in an one-stage surgery, with good results. In order to chose the right treatment option scapular kinematics must be taken into consideration especially when acromial fractures are associated with rotator cuff tears.*

Keywords: *shoulder, rotator cuff tear, acromion, non-union*

INTRODUCTION

Fractures of the scapula range from 0.4 to 1% of all fractures, with acromion fractures representing 7% of all scapular fractures [1]. Usually though acromial fractures are rarely reported due to their low incidence [2]. Lesions associated with acromial fractures such as rotator cuff tear are even more rarely described [3]. An MRI performed for a rotator cuff lesion (Figure 1) may show an associated acromial fracture, whereas a CT performed to describe an acromial fracture/non-union will not show a rotator cuff tear [4].

Treatment methods

A direct consequence of low acromial fracture incidence is the fact that there is no clear consensus on repair options resulting, more often than not, in surgeons choosing treatment options which they have the most experience withat the same time without overseeing patients'demand levels [5,6]. There are many reported methods for acromial fracture fixation a variety of them being presented in the literature such as tension band wiring, screw and plate fixation techniques, Kirschner wire fixation and in each of them patient specific factors and associated lesions are always taken into consideration when choosing a treatment option [7-11].

[3] Bagdasar-Arseni Clinical Emergency Hospital, 12 Berceni Road, 041915, Bucharest, Romania

The surgical treatment has several complications, mostly locoregional, ranging from hematoma and infection to persistent pain irradiating to the distal arm and forearm, posing a problem especially in patients with associated ipsilateral medical conditions of the forearm or of the arm [12-14]. Letting surgical treatment aside there are at least two more important factors that need be considered when dealing with an acromial fracture and these are the complex3D anatomy of the acromion and the so called superior shoulder suspensory complex (SSSC) which is an important factor in the aftercare postoperative prognosis of acromial fractures [2,8,15-17]. The SSSC is not the only factor to consider, as a system of bursae and the deltoid muscle allows for the possibility of pain irradiating in the distal arm and forearm, making for a difficult differential diagnosis [18].

Figure 2: Intraoperative image showing the non union fragment of acromion being held with a Kocher clamp. In the secondary plane of view we can see the torn supraspinatus tendon and the humeral head. This image is from the author's personal database.

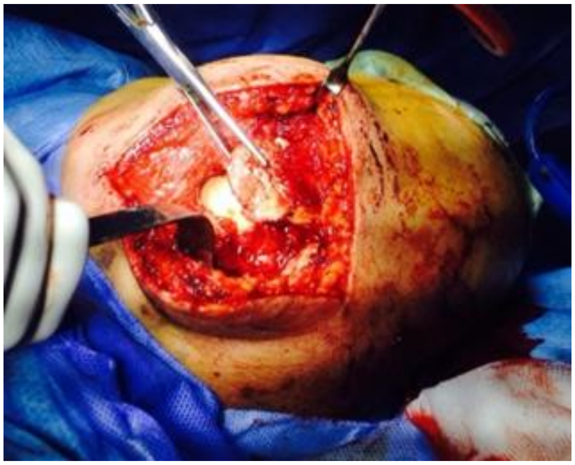

Figure 3: Intraoperative image showing the torn supraspinatus tendon being pulled into place with traction sutures, before reinsertion. This image is from the author's personal database.

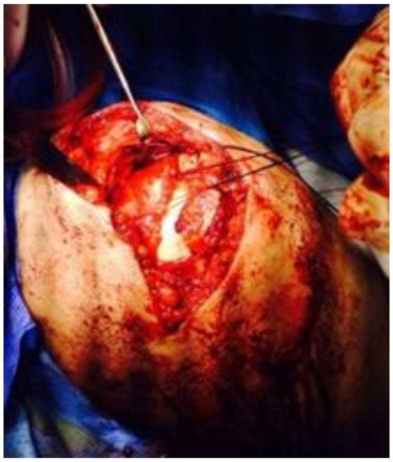

The complex 3D anatomy of the acromion makes it hard to fit any available plate system, most acromial plates requiring intraoperative bending in order to fit the required anatomy without excessive soft-tissue debridement while at the same time trying to maintain rigid fixation in an area of multiple pull vectors mainly arising from the deltoid and trapezius muscles [19-21]. When considering the complete management of acromial fracture non-union associated with rotator cuff tear (Figures 2, 3) one must take into consideration complex subjects like shoulder force vectors and SSSC implications in patient expected outcome.

DISCUSSIONS

As expected, the literature regarding rotator cuff pathology was found to be abundant, and a good number of articles were found regarding acromion non-union, but articles concerning the association of the two were scarce. Treatment recommendations varied, and were made on a case-to-case fashion.

The non-unions of the acromion can be treated in a variety of ways. In their 2006 article, Lumbreras et al describe the case of 56 year old male patient treated surgically with plating andautologus iliac crest bone grafting, with excellent clinical and radiologic results [23]. Liodakis et al report using the same method, but with an adapted distal radius plate; they offer a long follow-up of two years with measurable improvement in both range of motion as well as in the SSRS (Subjective Shoulder Rating System) Score [24].

Os acromiale

A differential diagnosis can be made with os acromiale, an unusual anatomic variant usually discovered incidentally [25]. In their 2016 article, Garcia et al define the os acromiale as a failure in the fusion of an accessory ossification nucleus of the acromion, and propose an arthroscopic method of fixation with cannulated screws, as opposed to the open technique [26]. Hurst claims an 8% incidence rate in his 2019 article, and advises for the careful diagnosis of this variant in all of the patients that are about to undergo shoulder surgery [27].

The accepted treatment methods consist of non-surgical management, open or arthroscopic fragment removal, open or arthroscopic reduction and fixation (bone grafting may be used) and arthroscopic subacromial decompression [28]. Failure to recognize an incidence of os acromiale may lead to confusion with an acromial non-union, as the imaging may be similar, but the patient's history and previous investigations may help with the differential diagnosis.

When looking for os acromiale, MRI findings on axial images generally report a relatively triangular unfused ossicle with an almost transverse interface with the acromion and irregular margins, with interface edema and marrow edema of the opposite bony structures [29]. At the same time, acromial non-unions possess similar characteristics on MRI (Figure 4), but key finding during history taking are crucial for diagnostic orientation, for example the lack of patient-reported shoulder trauma or bone disease like osteoporosis may incline the diagnosis towards os acromiale rather than acromial non-union [30]. In a symptomatic patient it is our opinion that the differential diagnosis has a theoretical purpose, as the treatment methods are similar.

CONCLUSION

In this rare occurence, a large rotator cuff tear with retracted tendons combined with an acromion non-union are usually repaired by an open technique in an one-stage surgery, with good results. In order to chose the right treatment option scapular kinematics must be taken into consideration especially when acromial fractures are associated with rotator cuff tears.

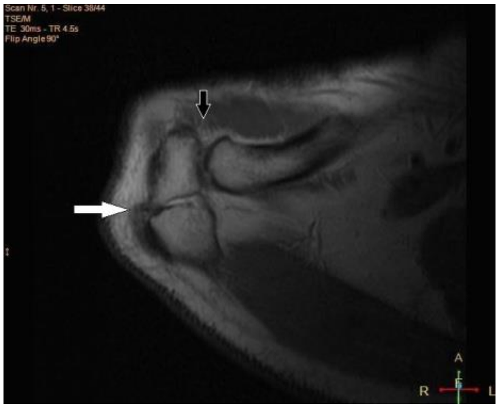

Figure 4: PDW_aTSE axial MRI image showing acromial non union (white arrow), easily confused with os acromiale. The acromioclavicular joint is indicated by the black arrow. This image is from the author's personal database

Outcomes of frozen embryo transfer in patients with and without ovarian hyperstimulation syndrome

Sima Mousavi[1], Masoumeh Hajshafiha[2], Tahere B. lak[2]

Abstract: *Introduction: One of the methods utilized to treat infertility is the use of frozen embryos. This technique is particularly employed in patients with ovarian hyperstimulation syndrome (OHSS), which leads to heightened blood estrogen levels. The purpose of this study was to compare the percentage of pregnancy and abortion between patients who used the frozen embryo method due to OHSS and others who practiced the same method for other reasons.*

Materials and Methods: This retrospective, cohort study was conducted on a total of 338 patients who visited in vitro fertilization (IVF) section of Kowsar Hospital of Urmia-Iran to employ the frozen embryo method (May 2013 to December 2015). The patients were classified into two groups, i.e. the OHSS group (N=150) and the non-OHSS group (N=188). Data were obtained and examined by evaluating the files in a questionnaire.

Results: The two groups did not differ significantly with regard to their mean age (p = 0.57). There was also no statistically significant difference between the OHSS and non-OHSS groups regarding the quality of frozen embryo transferred (P = 0.17). Also, there was also no statistically significant difference between the two groups in terms of their pregnancy rate (OHSS = 30.0% vs. non-OHSS = 25.0%) and miscarriage rate (OHSS = 31.11% vs. non-OHSS = 24.44%) (p = 0.32 and p = 0.31, respectively).

Conclusion: Ovum exposure to high estrogen during ovulation stimulation does not affect embryo implantation and miscarriage in patients with OHSS.

Keywords: *abortion, embryo, estrogen, frozen-thawed embryo transfer (FET), Ovarian hyperstimulation syndrome*

BACKGROUND

Infertility is characterized as the inability to conceive after 12 months of regular unprotected sexual intercourse in women aged <35 years and 6 months of regular unprotected sexual intercourse in women aged >35 years [1]. Studies have revealed that 8 to 12% of couples worldwide are facing fertility problems [2], accounting for nearly 72.4 million people in the world who are affected by infertility [3]. The World Health Organization asserts that infertility will become the world's third most prevalent disorder in the next few years preceded by cardiovascular diseases [4]. Study by Akhondi et al. showed the primary infertility rate to be 20.2% among Iranians [5].

There are various methods of infertility treatment including change of lifestyle, medications or surgery, and assisted reproductive technology (ART) [6]. Overall, as a costly assisted reproduction method employed in various countries, IVF (in vitro fertilization) is utilized by couples in a limited way on the other hand, the results of these methods have not been that fruitful [7].

The duration of uterine receptivity to blastocyst acceptance is highly dependent on estrogen levels such that this process lasts longer at low estrogen levels than at high estrogen levels [8]. That the uterine environment is not conducive to blastocyst acceptance occurring at high estrogen levels is the result of improper expression of the genes responsible for embryo acceptance to the uterus. With the use of the FET

(frozen embryo transfer) method, endometrial receptivity can be increased as the method eliminates the effects of estrogen on the endometrium produced by ovulation stimulation [9].

Nowadays, FET is regarded as one of the most prominent techniques of infertility treatment that enhances the cumulative rate of pregnancy. Additionally, FET lessens the cost of treatment, the rate of multiple pregnancies, and OHSS (ovarian hyperstimulation syndrome) [9]. In this method, upon stimulation of ovulation, removing oocytes, and insemination (i.e. embryo formation) in vitro, the formed embryos are frozen.

Despite the fact that the use of frozen embryo and its transfer to following cycles, in which the patient does not undergo ovulation stimulation and the estrogen level is not high, has removed the effect of estrogen on implantation in these cycles, whether or not the high rate of estrogen impacts ovulation stimulation, embryo quality, implantation, and embryonic growth and development is to be understood. The results of the study by Weinerman R et al. revealed that if an embryo is exposed to high estradiol levels, its development, and attachment to the endometrium are undermined [10]. Estradiol can influence the proliferation of human embryonic cells to the extent that the physiological levels of estradiol make it possible for stem cells to proliferate. However, estradiol at levels higher than physiological ones impairs stem cell proliferation, occurring through the lowered expression of the HDACI gene, which contributes to embryonic development [10,11].

This study was conducted to assess and compare the rate of implantation and abortion in patients who used frozen embryo transfer either due to OHSS syndrome or other reasons such as inadequate endometrial thickness, uterine bleeding, etc. Their embryos were frozen and transferred in subsequent cycles after endometrium was prepared. Then, we investigated the impacts of oocytes exposure to high estrogen on ovulation stimulation and its effects on the quality, implantation, and growth of the embryo in the uterine.

MATERIAL AND METHODS

The present study was implemented on patients who visited the IVF section of Kowsar Hospital in Urmia, Iran (May 2013 to December 2015). The data were accumulated by reviewing the files and in cases where patients' records were not complete, their data was collected through phone calls and face-to-face visits in the form of a questionnaire. This project was approved by the Ethic Committee of Urmia University of Medical Sciences, and was in accordance with the Helsinki Declaration.

The patients were divided into two groups in terms of why they wished to use embryo freezing. The first group comprised participants whose embryos were frozen due to OHSS (OHSS group), and the second group included participants who used the frozen embryo transfer method for reasons other than OHSS (non-OHSS group). One or two days after their second period time, patients referred from the first or second day after the second period of egg retrieval to prepare the uterus. From the second day of the cycle, they were treated with 2 mg Valerate Estradiol every 8 hours. If their endometrium was more than 8 mm thick and three-linear, they received 50 mg progesterone intramuscularly every 12 hours, along with estradiol at the same time. On the fourth day of their progesterone, their embryos were transferred, followed by estradiol, and progesterone. After 14 to 15 days, patients' β-HCG levels were checked. If positive, they visited the hospital for an ultrasound two weeks later. Also, patients were evaluated for miscarriages up to 20 weeks of gestation.

Inclusion criteria comprised: all patients who volunteered to undergo IVF, yet after ovulation and embryo formation, their embryo transfer was canceled and it was instead frozen due to reasons such as OHSS, uterine bleeding, inadequate endometrial thickness for embryo transfer, presence of polyps, or any uterine space lesion or cervical stenosis, etc., were included in the study. Exclusion criteria also were <8mm endometrial thickness on day 13, consumption of Valerate Estradiol or hyperechogenic, and homogenous endometrium on vaginal ultrasound on this day.

Statistical analysis

The statistical analyses were performed using the SPSS software version 16.0 for Windows (SPSS Inc., Chicago, IL). Categorical variables were summarized as numbers (percentages). The variables were compared between two groups by the Chi-square/Fisher’s Exact test. $p < .05$ were considered statistically significant.

RESULTS

Of the 338 patients analyzed, 150 were patients with OHSS, and 188 were non-OHSS. Out of 150 OHSS patients, 46 had positive pregnancy, one of which one patient was excluded due to chemical pregnancy and 45 had positive pregnancy results (30.20%). Of 188 non-OHSS patients, 48 had positive pregnancy, of which 2 and 3 patients were excluded due to chemical pregnancy and EP, respectively, and 45 had positive pregnancy (25.13%). Nonetheless, no EP incidence was reported in OHSS patients. Of 45 patients with OHSS, 11 had a miscarriage (24.44%) and 34 continued their pregnancy after 20 weeks (75.55%). Of 45 non-OHSS patients, 14 had miscarriages (31.11%) and 31 had continued pregnancies after 20 weeks (65.95%) (Figure 1).

Figure 1: Flow chart of included subjects

Miscarriage (N=11)
Continued pregnancy after 20 weeks (N=34)
Chemical pregnancy (N=1)

The mean age of the research population was 30.13 ± 5.5 years (OHSS = 29.91 ± 5.67 years and control = 30.35 ± 5.4 years (p = 0.57)).

A total of 338 patients experienced frozen embryo transfer, 2 embryos transferred in the OHSS and the non-OHSS groups, respectively. When assessing the quality of transferred embryos, 66.86% and 69.07% of embryos belonged to patients with OHSS and non-OHSS groups, which had embryos A and B, respectively. This finding was not statistically significant (p = 0.17).

Concerning the pregnancy rates from transferred embryos in patients between the two groups, 45 out of 150 OHSS patients (30%) had positive pregnancies, while 47 out of 188 (25%) non-OHSS patients had positive pregnancies, suggesting no significant difference between the two groups in terms of pregnancy rates (P = 0.32). Regarding the rate of miscarriage in patients with positive pregnancy, there was no statistically significant difference between non-OHSS patients (14 cases out of 45 cases, 31.11%) and the OHSS group (11 cases out of 45 cases, 24.44%) (P = 0.312). There was no significant difference between the two groups in terms of chemical pregnancy rate (0.66% in OHSS group versus 0.5% in the non-OHSS group) (p = 0.85). Two ectopic pregnancies were found in non-OHSS patients, whereas ectopic pregnancy did not occur in OHSS patients (p = 0.50).

DISCUSSIONS

Despite substantial efforts made to prevent it, OHSS remains an iatrogenic disorder with potentially life-threatening complications [12]. The most significant way to stop OHSS is prevention, and one of the major ways to prevent it is avoiding embryo transfer in these patients, and instead, freezing and transferring the embryo in future cycles with no ovulation stimulation is an important method in preventing this major problem. Using FET in these cycles makes a great contribution to reduced incidence or severity of OHSS. Moreover, it decreases the adverse effects of high estrogen on embryo implantation [6]. The purpose of this study was to assess and compare the pregnancy and miscarriage rates among OHSS and non-OHSS patients in order to indirectly examine the effects of high estrogen on embryo implantation and growth in the patients. In the present study, an examination of the percentage of pregnancies in both groups revealed that high estrogen during ovulation stimulation has no impact on oocyte and embryos formed for implantation and early embryo growth and development in the uterus. On the other hand, it did not affect miscarriage either.

Studies have revealed that endometrial receptivity is highly reliant on estrogen levels since, at high estrogen levels, the uterus is not conducive to embryo implantation. Nevertheless, the impacts of high estrogen on embryo implantation and growth in OHSS cycles are yet to be known [13,14]. In a study, it was confirmed that high estrogen levels can undermine the proliferation of embryonic stem cells, hence its adverse effects on embryonic growth and development [10]. Meanwhile, the differentiation of the embryo for the implantation process is an important factor in the occurrence of pregnancy [13].

Check et al. examined the patients whose fresh embryo transfer was canceled due to OHSS or deficient endometrial thickness, and instead underwent the frozen embryo method. The rates of clinical pregnancy and live birth in OHSS patients were 42.8% and 31.9%, respectively, whereas the values were 28.7% and 21.8% for non-OHSS patients (insufficient endometrial thickness), respectively. As is shown, the rate of pregnancy and live birth in the non-OHSS group is significantly lower than that of the OHSS group ($P = 0.01$ and $P = 0.07$, respectively) [15].

Raziel et al. assessed the rate of premature miscarriage in OHSS patients undergoing IVF. Conducted on 104 patients with severe OHSS, this study revealed that 58% of these patients were pregnant, of which 38% had miscarriages. Compared to non-OHSS patients who practiced IVF, the pregnancy rate among OHSS patients was significantly higher, which was seemingly due to the non-OHSS patients' higher mean age. in this study, the rate of miscarriage in patients with OHSS was higher than the control group, i.e. non-OHSS group, which was not consistent with findings of our study [16].

With regard to the outcome of pregnancy in Check et. al, the live birth rate in the OHSS group was 31.9% compared to 21.8% in patients with less endometrial thickness, which was also statistically significant [15]. In the study by Howarth and et al., the rate of live births in the first and fourth groups was lower than in the second, third, and fifth groups, which was also statistically significant [17]. Nonetheless, in our study, which assessed pregnancies up until the 20th week of pregnancy, the groups were compared only in terms of their rate of miscarriage such that in the second non-OHSS group's patients, the rate of miscarriage was higher than in OHSS patients, yet there was no statistically significant difference between the two groups. The present study also had its own limitations. Due to the lack of information in the files and unavailability of some patients, which decreased the number of samples in this study, more comprehensive and longer-term prospective studies are required to increase the power and reliability by expanding the number of samples and controlling the study as much as possible.

CONCLUSIONS

Accordingly, the results of our study potentially show that oocytes exposure to high estrogen during ovulation stimulation has no impact on oval and embryos formed for implantation, growth, and development in utero.

Pharmacological evaluation of glomerulonephritis in Covid-19 patients

Jalal Nourmohammadi[1], Mohsen Akhondi[2], Fereshte Rajabiniat[3], ZahraSadat H. Vaeaz[4], Zahra Nourmohammadi[5], Mahdieh H. Moghadam[6]

Abstract: *Acute kidney injury (AKI) and glomerulonephritis can be complications in COVID-19 patients, which is announced with widely incidence rates in different investigations and is determined to have a major effect on the prognosis of the disease. There are considerable variations in AKI and glomerulonephritis rates between other countries. The rate is generally lower than in Western Europe and the United States in China. Heterogeneity in different racial and ethnic lines can be a potential explanation. This investigation systematically reviews the scientific resources regarding AKI and glomerulonephritis among hospitalized COVID-19 patients. Both observational and interventional investigations(including case reports) with English full-text provide essential data, with no limitation in release or peer-review. More evidence is required to assess the AKI, especially glomerulonephritis in Covid-19 patients, for better management of Covid-19.*

Keywords: *COVID-19, AKI, patient, glomerulonephritis*

INTRODUCTION

The kidneys play an important role in regulating acid-base balance, water and electrolyte balance, nitrogen balance, and calcium and phosphorus metabolism. Chronic Kidney Disease (CKD) is a disease that is caused by the progressive and irreversible destruction of the number and function of nephrons by various factors. Among the most important of these factors are diabetes, hypertension, glomerulonephritis, and polycystic kidney disease, respectively. Causes of chronic kidney disease reduce the number of nephrons through progressive destruction of nephrons, in which case the amount of blood flow and pressure in the remaining healthy nephrons increases, and thus the remaining nephrons increase their function (Figure 1). Try to keep the Glomerular Filtration Rate (GFR) within the normal range; For this reason, after a while, the remaining nephrons become hypertrophic due to overactivity, and eventually, this compensatory mechanism causes glomerular sclerosis, resulting in the destruction of glomeruli and the disappearance of the remaining nephrons.

In patients with chronic kidney disease, especially in its advanced stages, transient complications such as nausea, vomiting, anorexia, hyperkalemia, metabolic acidosis, hyperphosphatemia, fluid retention, hyperparathyroidism, bone disorders, cardiovascular and pulmonary disorders, neuromuscular disorders, normochromic normocystic anemia, hypersensitivity to infection, gastrointestinal disorders, metabolic-endocrine disorders (lipid abnormalities), Inflammation and oxidative stress occur. Kidney problems are directly related to the nutritional status of patients.

The prevalence of energy-protein malnutrition in these patients is very high. Numerous studies have shown that the life expectancy of these patients increases with the improvement of nutritional status. According to various studies, the COVID-19 infects all groups of different ages include: newborns, pediatrics, young people, elderly, but some groups are more vulnerable to this infection.

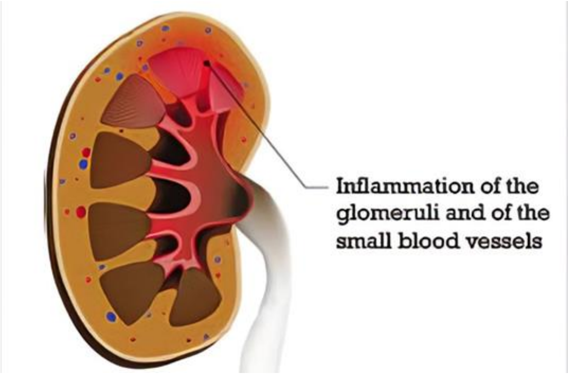
Autoimmune patients are one such group [1,2].

Figure 1: Test your knowledge on glomerulonephritis



Inflammation of the glomeruli and of the small blood vessels

Despite most of the cases presented with mild symptoms so far, many of them experienced lethal complications, including organ failures, acute respiratory distress syndrome (ARDS septic shock, and pulmonary edema. Acute kidney injury (AKI) is one of the complications in patients with COVID-19, which is detected as a widely varied incidence rate in various investigations and is observed to have a significant effect on the prognosis and outcome of the disease [3-9]. Many reports from China, Europe, and the United States expressed the characteristics and outcomes of acute kidney injury among hospitalized patients with COVID-19 [8,9]. The pathophysiology of COVID-19 related to glomerulonephritis is not determined by a specific theory up to date. It is recommended that the cause of kidney injury be multifactorial; for example, cardiovascular and sepsis, hypovolemia, and nephrotoxins are critical contributors [10]. The study described the incidence of acute kidney injury as a feature of thrombotic microangiopathy (TMA)-like phenomenon, secondary to infection of SARS-CoV-2 [11]. Moreover, viruses particles in renal endothelial cells lead to viremia as a possible reason for endothelial damage in the kidney and a potential contributor to glomerulonephritis and acute kidney disease. Other mechanisms of action may be the direct infection of the renal tubular epithelium and podocytes via an angiotensin-converting enzyme 2 (ACE2)-related pathway in patients with Covid-19 (Figure 2), which can lead to the formation of protein reabsorption vacuoles, mitochondrial dysfunction, acute tubular necrosis, protein leakage in Bowman's capsule, and collapsing glomerulopathy [12].

METHODS

Inclusion and exclusion criteria

Observational and interventional investigations (e.g., case reports) with English full-text with presenting data for analysis were included in our study with no limitation in time of publication. Exclusion criteria are review articles and other types of publications with no patient enrollment, articles that specifically focus on the pediatric population, pregnant women, and studies with insufficient evidence on glomerulonephritis occurrence.

Protein catabolism and nitrogen balance in patients with CKD are directly related to energy intake. Inadequate energy intake increases the process of protein catabolism and causes a negative nitrogen balance. Many studies have shown that basal metabolic rate in CKD patients is lower than in others. In dialysis patients, the basal metabolic rate increases by 12-20%, so adequate energy intake in these patients is very important because low carbohydrate (glucose) intake in the diet puts the body in the phase of gluconeogenesis and depletes glycogen stores. Liver and conversion of muscle proteins to glucose, the body is in an unfavorable metabolic state. In other words, proteolysis increases the catabolism of proteins by causing metabolic acidosis and causes the breakdown of muscle mass. Lack of adequate physical activity is also effective in muscle atrophy. In addition, increased production of nitrogen products in the blood causes symptoms such as anorexia, nausea, which is effective in reducing food intake by the patient and maintaining the unfavorable conditions of catabolism. In patients with chronic renal failure, impaired renal function also increases blood triglycerides, impaired carbohydrate metabolism, insulin resistance, and diabetes by increasing the production of inflammatory cytokines and altering the secretion of endocrine hormones. Sometimes severe dietary restrictions in these patients can also lead to malnutrition. Establishing a proper diet is essential to prevent malnutrition in patients with kidney failure. These patients usually need 30-35 cal/kg/IBW of energy per day. The ratio of macronutrients in the diet of these patients is usually as follows: The need for protein in patients with chronic renal failure depends on the function of their kidneys. For example, in patients with 50% renal function and blood creatine levels less than 2 mg/dl or GFR above 70 ml/min, the need for protein is 0.8-1 g/kg/d and in patients with 20-50% Renal function and blood creatine level 2-5 mg/dl or 25-70 ml/min GFR protein requirement 0.6 g/kg/d in hemodialysis 1-2 g/kg/d and in peritoneal dialysis 1-1.5 g/kg/ d, carbohydrates are considered 55-70% and fats are considered 30-30%. Usually the need for fluids in these patients is 600-500 ml + volume of excreted urine + abnormal loss of water from non-renal routes. However, in patients with chronic renal failure in the pre-dialysis phase, there is no need to calculate the volume of fluid intake unless the patient has severe edema. The amount of electrolytes and minerals required depends on the patient's nutritional status and the extent of kidney damage. For example, in an oligarchy patient (urinary excretion less than 500 cc per day), severe sodium, potassium, magnesium, and phosphorus restrictions should be imposed on the diet. In some of these patients, the use of commercial formulas is recommended to meet their maximum nutritional needs. Typically, commercial formulas for kidney patients with high calorie density (2.8-8 kcal/ml), low protein (81-70 g/l), sodium (700-1000 mg/l), potassium (1600 mg/l) - 1000) and phosphorus (600-700 mg/l) are considered. The need for vitamins in patients with kidney failure depends on the type of diet. Patients with severe dietary restrictions need water-soluble vitamins. Normally, the levels of vitamin B1, folic acid and vitamin C in these patients are lower than normal. Hemodialysis patients are usually deficient in vitamins A, vitamin D and B12, and it is recommended to take these vitamins as supplements. Also, when the kidneys fail, the synthesis of 1 and 25 dihydroxycholecalciferol in the kidneys decreases and this vitamin needs to be prescribed. Iron is one of the minerals that is essential in these patients. It is usually recommended to take 10-15 mg/d of iron, but in kidney patients with ferritin levels below 100 mg, it is necessary to take at least 60 mg of ferrosulfate. It is recommended to take iron supplementation with citrus juice in these patients to increase iron absorption. One of the most common problems in kidney patients is metabolic acidosis, which requires oral bicarbonate to maintain blood pH in these patients. In addition to using a proper diet, encouraging the patient to increase physical activity is effective in increasing the expression of anti-inflammatory proteins, improving the sensitivity of insulin-like growth factor, increasing the production of muscle fibers and preventing the breakdown of muscle mass.

Data extraction

Search results were assessed by two independent authors, and study selection was performed assessing the title and the abstract. Among selected publications, full-text articles were evaluated to determine the eligibility for inclusion. . In the end, Discrepancies were resolved by consensus. The following information was extracted from the articles using an organized checklist: name of the first author, date of the publication, name of the journal, study location, study designs, the definition of, age range, gender ratio, and proportion of glomerulonephritis occurrence. General information of the included articles was reviewed precisely to prevent duplication and data overlap.

RESULTS

A total of 289 articles were identified through the systematic search of the databases, as previously mentioned. After removing all duplications, 259 records remained and were carefully examined, which returned an Evaluation of the full-texts to check the eligibility was performed, and 198 publications were excluded due to either not meeting the inclusion or exclusion criteria. From 61 remaining articles, ten were excluded due to data overlap. Finally, 13 studies were selected and included in the review. The process and results are outlined in Figure 3. Some articles defined AKI according to KDIGO criteria as an increase in serum creatinine by 0.3 mg/dL or a 50% level rise in serum creatinine from baseline within seven days. AKI was defined roughly by serum creatinine cut-off if specified in other studies. The diagnosis of glomerulonephritis in Covid-19 patients was confirmed via biopsy tests. The included studies are demonstrated in Table 1 and Table 2.

What are the symptoms of urinary tract infections in children?

"Fever in young children may be the only sign of a urinary tract infection,". Due to the lack of more obvious symptoms, when girls younger than 2 years old or uncircumcised boys younger than 1 year old have a fever, many medical associations recommend urine culture. "Babies may not eat well, vomit, sleep more, or show signs of jaundice,". In older children, urinary incontinence (loss of bladder control) may occur again; symptoms of a urinary tract infection are often not seen in the elderly; these symptoms may be vague and accompanied by malaise, and the only symptoms present are a change in mental state or fatigue. Bagheri added: "Although in some cases, the first sign that a health care provider encounters is a blood infection or infection in the blood; The fact that many older people already have impotence or dementia may complicate the diagnosis.

During the recovery from acute kidney failure, your gastroenterologist may prescribe special meals to help support and limit your kidney function. Your doctor may refer you to a nutritionist who can analyze your current meals and suggest ways to prepare meals that put less strain on your kidneys. Depending on your situation, your nutritionist may suggest the following: Choose foods with less potassium. Your dietitian may suggest that you choose low-potassium foods. Foods high in potassium include bananas, oranges, potatoes, spinach, and tomatoes. Examples of low-potassium foods include apples, cabbage, green beans, grapes and strawberries. Avoid products with added salt. Get less sodium by avoiding products with extra salt every day. These foods include many ready-to-eat foods, such as frozen foods, canned soups, and fast foods. Other foods with added salt include salty snacks, canned vegetables, and processed meats and cheeses. Limit phosphorus intake. Phosphorus is a mineral found in foods such as milk, cheese, nuts, nuts and peanut oil. High levels of phosphorus in the blood can weaken bones and cause itchy skin. Your dietitian can give you tips on how to limit phosphorus in your specific situation. As your kidneys improve, you may no longer need to follow a specific diet, although a healthy diet is still important.

DISCUSSION

Early diagnosis of MGN is desirable because it is different from other nephropathies, especially secondary nephropathy, which is caused by causes such as tumor, infection, drug toxicity, or other autoimmune diseases such as systemic lupus erythematosus. Of all cases, 20-30% are MGN due to secondary factors and the remaining 70-80% are classified as primary. Reliable diagnosis of both forms of the disease is important because of differences in treatment: primary MGN is treated with immunosuppressive drugs, while secondary MGN is treated by targeting the causative agent. MGN is detected by a kidney hole followed by a histological test or electron microscopy (to identify immune complexes in the glomeruli). In order to make a final diagnosis of primary MGN, secondary factors must be eliminated, which saves time in the diagnosis process, for example, tumor screening must be performed. In some patients, MGN can be identified as a secondary cause before it is created, which complicates diagnosis and treatment decisions. Primary MGN should be distinguished from other autoimmune diseases involving the kidney, such as lupus nephritis, vasculitis associated with antibodies against neutrophil cytoplasm (ANCA), and Goodpasture syndrome.

In December 2019, Since the COVID-19 emerged in Wuhan city of China and quickly spread throughout the world, it has remained the most prominent health problem all over the world [5]. Our knowledge about this disease is still evolving, and the combination of studies and reports yields a more understanding as time goes on. We investigated a systematic review of the studies that reported glomerulonephritis in hospitalized COVID-19 patients. Treatment of glomerulonephritis include:

1- If your blood pressure is high, your blood pressure will drop with limited water and sodium.

2- Antihypertensive drugs are also used if the blood pressure is high.

3- Proteins of high biological value should be given to improve the nutritional status of the patient.

4- Treat a urinary tract infection immediately.

5- Use diuretics to reduce fluid load.

6- In case of severe edema, raise the head of the patient's bed for more comfort and better urination.

7- Weigh the patient daily.

8- Adjust the patient's sodium and water intake based on the patient's kidneys' ability to excrete water and sodium.

9- Iron and vitamin supplements are given if there is anemia.

10- Cortisone or cytotoxic drugs if the disease is severe.

11- In the early stages of the disease, dialysis is performed in order to improve the patient's physical condition, prevent water and electrolyte imbalance and reduce the risk of complications of renal failure.

CONCLUSION

A report (from China) had even concluded that acute kidney injury (AKI) is not a complication of COVID-19. However, the following evidence modified this perspective. Although, many researchers announced the lower rates of AKI (which may lead to glomerulonephritis) from China compared with elsewhere. These evidence indicated that kidney damages like glomerulonephritis could be a common complication of the Covid-19. Compared to previous reports, our investigation found many case reports of Covid-19 patients with glomerulonephritis, which is demonstrated in table 2. This systematic review was conducted to evaluate glomerulonephritis in Covid-19 patients. Further investigations are warranted to precisely determine whether glomerulonephritis is a complication of COVID-19 or not. However, according to present studies, Covid-19 may lead to several kidney injuries, including glomerulonephritis.

Pre-surgical management of primary leiomyosarcoma of the bone

George M. Avram[1], Cezar I. Calin[2], Mihnea Dobre[1], Miruna Harabagiu[3], Cristian Peneoaşu[3], Diana M. Marcu[4]

Abstract: *Leiomyosarcoma is a rare type of smooth muscle cell tumor, with an incidence of 7-10% compared to other types of sarcomas. It develops primarily in the retroperitoneal cavity, the genital tract and extremities. Leiomyosarcoma can also affect the bone, either as a primary tumor or as metastasis. Primary osseus leiomyosarcoma is a rare finding in patients with radiologically identified osteolytic lesions having an incidence of <1% of total primary bone tumors.Due to its low incidence patients with primary osseous leiomyosarcoma are never diagnosed before immunohistochemical analysis and case management is difficult because of the lack of specific indications pertaining to primary osseus leiomyosarcoma. Data on age specific incidence is scarce but there seems to be a tendency towards a higher incidence with advanced age.*

The purpose of this work is to discuss the complete management of primary osseus leiomyosarcomas based on interdisciplinary medical teams' indications in a Romanian hospital setting.

Keywords: *primary leiomyosarcoma of bone, immunohistochemical analysis, case management*

INTRODUCTION

Primary osseous leiomyosarcoma was first described in 1965 as a malignant tumour arising in the proximal left tibia of a 73 year old patient [1].

An exact reported incidence is unknown due to the scarcity of cases but out of the total amount of primary malignant tumours of the bone, primary leiomyosarcoma is listed together with Ewing and other sarcomas as having a <1% annual incidence [2]. Twenty-eight case have been reported in the USA between 1965 and 1990, however the number rose to a total of 120 cases between 1990 and 2005 and by 2020 many more authors reported their experience with this type of tumour as well as outcomes and prognostic factors [3,4,5,6,7]. Rising reported cases are most likely due to the widespread use of immunohistochemistry.

To date, there is no clearly defined prevalent location of primary osseous leiomyosarcoma but a nationwide study of 104 patients diagnosed with leiomyosarcoma during 1975 and 2009 reported the femur, pelvis and tibia as the first three most common locations [5]. Regarding age and gender distribution of leiomyosarcoma, no clear pattern was identified, although a nationwide study based on the French network of cancer registries reported an ascending incidence rate up to 35% incidence in the 40-64 years age group declining thereafter to 27% in the 75+ years group while gender distribution seems to incline to a higher reported incidence in females [7].

Certain diagnostic is based on combined histopathological and immune histochemistry exams with histological grading and surrounding tissue invasion being the key elements for long-term prognosis [3,4].

Surgical options range from fine needle biopsy to locoregional excision and limb amputation. Function is severely compromised by amputation, although there are on-going efforts to develop artificial limbs [8] and to integrate them with the remaining limb stump [9,10].

A patient will present for an orthopaedic examination with

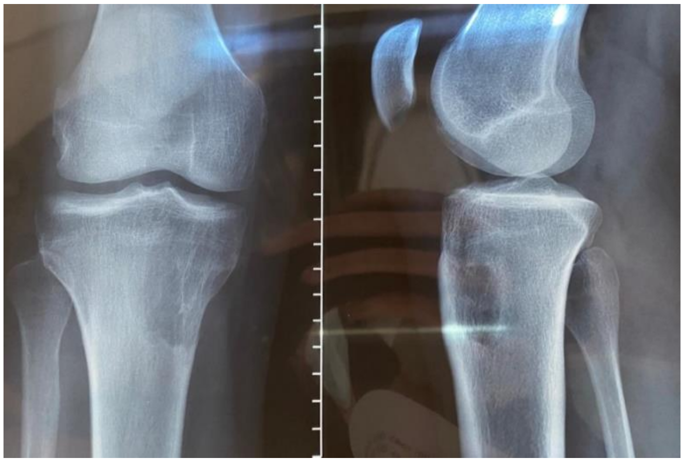
pain in a localised area, for example the proximal tibia, with no or scarce other local or systemic clinical signs, except for a painful elevation gradually appearing on the proximal tibia. Physical examination may show a tumorous formation located at the proximal tibial level presenting with renitent consistency and adherence to adjacent tissue.

Radiological findings

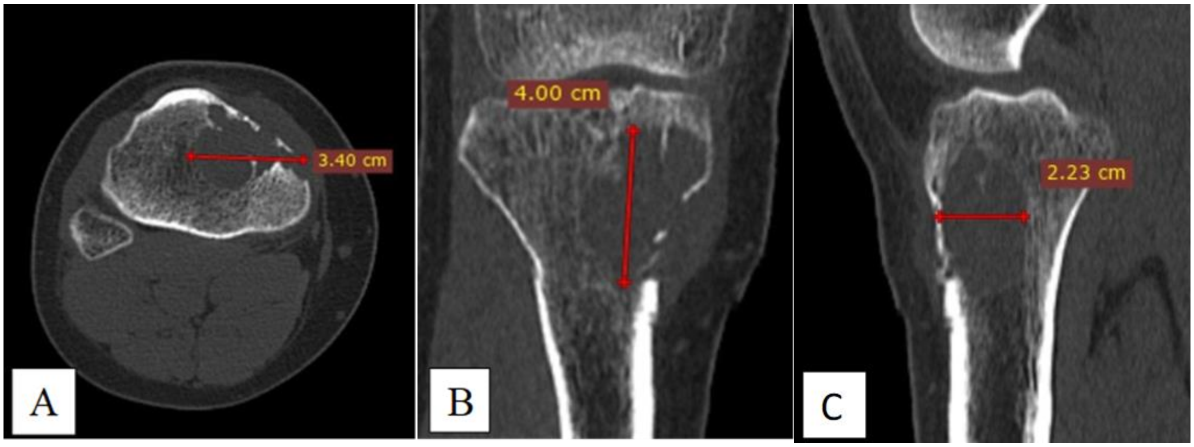
Physical examination would be followed by standard anteroposterior and latero-lateralradiographic exam of the affected segment, in our example, the knee and proximal calf (Figure 1). Radiographic results may reveal an osteolytic lesion localized at the transition zone between the proximal metaphysis and epiphysis of the tibia, with a mild extension towards the tibial shaft and with a taller than wider aspect. The margins may not be clearly defined and there may not be peripheral sclerosis. Erosion and narrowing of the medial cortex may be shown. Bone marrow may have a lobulated aspect but no extra-axial marrow growth. No periosteal reaction nor other bone structural changes may be found.

Figure 1: Right knee anteroposterior and lateral radiographs, suggestive of osteolytic lesion on the proximal metaphysis of the tibia.



Solely based on the radiographic examination, reported results may reveal both benign and malignant features. The benign feature would be represented by the lobulated structure of the bone marrow. The malignant features would be represented by the absence of peripheral sclerosis which would be suggestive of a rapidly evolving lesion and by the absence of periosteal reaction which would signify a fast growing mass.

Figure 2: A – axial sequence of the proximal tibial metaphysis showing osteolysis and extraosseous invasion; B – coronal sequence of the proximal tibial metaphysis; C – sagittal sequence of the proximal tibial metaphysis



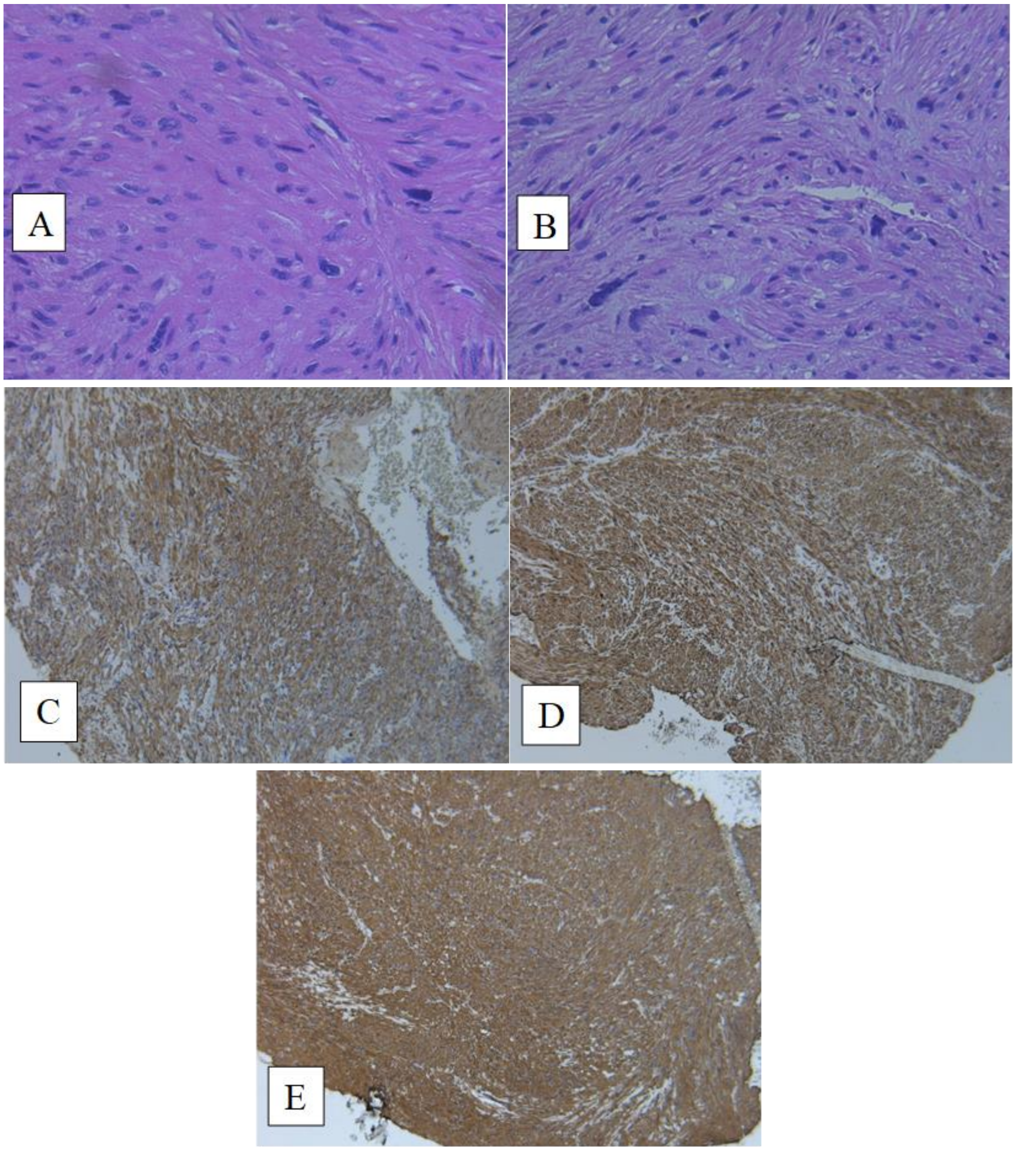
Following the radiographic examination a native CT scan (Figure 2) would be performed, that may be describing an osteolytic lesion, with no clear outline and irregular shape, localised at the proximal metaphyseal-epiphyseal junction of the tibia. The lesion may interrupt the medial cortex and may not affect the articular outline. Based on compared densities, tibial intra-axial trabecular bone signal may be identified within the ingrown mass. The left over trabeculae would be a result of a fast growing osteolytic lesion. Infiltration of the soft tissue, absence of periosteal reaction, as well as the absence of adenopathy in the popliteal fossa may be observed.

Such CT findings strongly would suggest the presence of an aggressive osteolytic tumour.

Histopathological exam

In order to confirm the diagnosis, an incisional biopsy will be performed and the sampled tissue will be sent for histological examination (Figure 3). Results may reveal a sarcomatous proliferation composed of fusiform, elongated cells, arranged in a storiform fashion, forming fascicles that intersect at sharp angle; hyperchromatic ovoid, elongated nuclei, that present abnormal variations and frequent mitoses (7-8 mitoses/10 HPF) and extended necrotic areas; absence of osteoid matrix may also be noticed. Following histopathological examination a immunohistochemical exam will be recommended.

Figure 3: A – histopathological analysis with haematoxylin and eosin stain, x200, with typical aspects for sarcoma; B –histopathological analysis with haematoxylin and eosin stain, x200, showing multiple faults and mitoses; C – immunohistochemical analysis, diffuse positive for desmin; D – diffuse positive for caldesmon and E – diffuse positive for smooth muscle actin (SMA).



Following immunohistochemistry examination (Figure 3) the tissue sample may be found to be positive to the following immunohistochemical markers: smooth muscle actin (SMA), caldesmon (+), desmin (+), special AT-rich sequence-binding protein 2 (SATB2) (+), 60% (+) ki67, (-) CD34, (-)transducin-like enhancer of split 1 (TLE1), (-) S100.

Immunohistochemistry tests will be correlated with the histopathological exam and together sugget the final diagnostic of leiomyosarcoma of bone, G2 stage–moderately differentiated. Staging is based on the Fédération Nationale des Centres de Lutte Contre le Cancer indications (FNCLCC)[11].

The correlation of imaging, histopathological and immunohistochemical results would lead to the formation of a interdisciplinary team of medical experts for the management of this case. The next step would be to perform a full-body native CT scan in order to rule out the presence of other primary site leiomyosarcoma locations that could bea source of metastases and could reclassify the proximal tibial lesion as not a primary osseous leiomyosarcoma but rather a metastases from a leiomyosarcoma formed elsewhere. After a full-body native CT scan would be performed, results may report no other identified lesions effectively establishing the final diagnosis of primary leiomyosarcoma of bone.

Because leiomyosarcomas have such a low incidence and difficult to interpret radiological and histological results, together with a poorly established prognosis, treatment options that best fit these types of cases would be dependent on the surgical and oncological team's experience. A multidisciplinary team is needed in order to synchronize radiotherapy and chemotherapy with surgery, as well as for establishing the proper conditions for psychological support. Also, as an attempt to preserve the affected limb, a tumoral reconstruction prosthesis would be indicated. In order to diminish the risk of local recurrence, the multidisciplinary team would also recommend one session of external neoadjuvant radiotherapy of 50Gy followed by surgical excision, prosthesis implantation and administration of adjuvant chemotherapy consisting of a dose of 5000mg/ m2ifosfamide (IFO) associated with intra-venous (i.v.)mesna for 24h infusion and doxorubicin (DOX) 60mg/m2i.v. (short infusion). Six sessions of adjuvant chemotherapy would be recommended by the oncological team to be administered once every 3 weeks (DOX + IFO x 6, q3w). Filgrastim would also be recommended by the oncological team in order to stimulate granulocyte colony-forming cells as a single administration of 5 mg/mL dose at least 24 hours after chemotherapy. The purpose of these recommendations is to reach local cancer margin control after neoadjuvant radiotherapy and to eradicate any minimal residual disease with adjuvant chemotherapy and to diminish the risk of metastases.

DISCUSSIONS

Numerous studies report variable results of leiomyosarcoma treated with chemotherapy and radiotherapy [12-15]. Radiotherapy was found to have useful results in controlling tumour margins especially in R0 and R1 reported margins [13,16,17]. This being said the multidisciplinary team may consider appropriate to recommend neoadjuvant radiotherapy of up to 50Gy in order to account for any possible microscopic tumoral cells that might remain. Together with neoadjuvant radiotherapy good results were obtained by adding surgery and adjuvant chemotherapy consisting of doxorubicin and ifosfamide [5,18,19]. In order to obtain the best possible long-term outcome a tumoral prosthesis would be recommended by the team for these cases.

Among all the treatment protocols with good outcomes that have been reported in literature, we should bring to mind the association of ifosfamide and doxorubicin with filgrastim 24 hours laterfor stimulating granulocyte colonies in order to permit chemotherapy amplification [15,20].

At the same time it is worth mentioning that the chemotherapeutical doses are not standardized and, thus, we would like to remark the possibility of lowering the dose of ifosfamide in order to raise the dose of doxorubicin, and at the same time to maintain the myelosuppression within the desired limits, and to offer a better response in correlation with dosage [18,21]. For leiomyosarcoma cases we could take into consideration other therapies, such as gemcitabine or gemcitabine-docetaxel association, mitomycin-doxorubicin-cisplatin triple therapy or administration of epirubicin in association with ifosfamide [14,22]. Regardless of the chosen therapy, it is important to mention the fact that the complete response to chemotherapy has not exceeded 8% of the total amount of patients who were treated with a known therapy plan and similar results have also been obtained for partial response to chemotherapy [22,23].

CONCLUSIONS

In conclusion, complicated, rare primary bone leiomyosarcoma cases do not have a stable management recommendation as of yet and are best treated by a multidisciplinary team which, most often than not, bases its recommendations on the established leiomyosarcoma treatment. The scope of this paper was achieved, by presenting the full pre-surgical management of such a tumour, with a focus on the importance of immunohistochemical exam, full-body CT for metastases exclusion and oncological treatment which may be doxorubicin and ifosfamide combined with mesna and Filgrastim.

Acknowledgements

We would like to thank col. Dr. Marius Dumitrescu for his open and helpful approach in providing important expert advice during the writing of the histopathological section of this paper.

We would also like to thank Edna Iordache (MD) for her given feedback during the writing process.

Predictive value of serum level of B type Natriuretic Peptide (BNP) in neonatal sepsis

Mirhadi Mousavy[1], Ahmad J. Khosroshahi[2], Sepideh Shadravan[3]

Abstract: *Background: NT-proB-type Natriuretic Peptide (BNP) (NT-pro BNP) is one of the biomarkers that has been studied in recent decades in connection with pediatric heart failure (HF) and congenital heart disease (CHD). Recently, infants hypothesized that serum. NT-pro BNP levels might be a good predictor of septicemia severity and response to treatment and prognosis in these patients. This study investigated the relationship between serum natriuretic type B peptide level and neonatal sepsis.*

Materials and Method: In this case-control study, all full-term and pre-term neonates admitted to children's Hospital, Tabriz-Iran(2021), with sepsis and a septicemia diagnosis were confirmed after obtaining consent. The study was deliberately entered by the patient's parents or legal guardian. Complete Blood Count with Differential (CBC/Diff), C - reactive protein (CRP) , Bacterial Culture (B/C) , Urine Analyze(U/A),Urine Culture (U/C) ,NT-pro BNP were checked and finally compared with laboratory results of the same number of infants who did not have clinical and laboratory symptoms of sepsis. After collecting samples, laboratory results, including serum levels of NT-pro BNP, were compared in case and control groups.

Results: One hundred patients were studied in two groups. Thirty-eight patients (38%) were boys, and 62 patients (62%) were girls. The mean age of the patients was 7.58±7.46 days. The mean weight of the studied patients was 2811.80±620.33 grams, with a median of 2855 grams. The most common clinical symptom observed in patients in the case group was fever (100%) followed by Poor feeding (84%). In the control group, all patients had jaundice. Neonates with sepsis had significantly higher initial pro-BNP values than the control group (10023.80 vs. 2247.20; p=0.001). The NT-pro BNP level cut-off point in predicting the final treatment status and mortality of neonates with sepsis was 9583 pg/ml with 97.7% sensitivity and 93.6% specificity.

Conclusion: Measurement of serum level of NT-Pro BNP in neonates with sepsis at the time of clinical signs with 97.7% sensitivity and 93.6% specificity with a cut-off point of 9583 is an important prognostic factor in the therapeutic management of patients.

Keywords: *septicemia, neonates, sepsis, mortality, natriuretic brain peptide*

INTRODUCTION

B-type natriuretic peptide(BNP is a natriuretic peptide with 32 amino acids and a ring structure, which is secreted from the atria and ventricles of the heart in response to changes in pressure or overload of heart chambers. NT-pro BNP (N terminal of the prohormone brain natriuretic peptide) is a marker of BNP in the blood. The mechanism of action of BNP is by activating Natriuretic peptide receptor-A (NPR-A) and increasing the production of Cyclic guanosine monophosphate (cGMP), which has a diuretic effect and dilation of pulmonary arteries [1,2]. BNP is a rapid and highly sensitive marker in myocardial disorders. It also plays an essential role in the organogenesis of the fetal heart and the stage of fetal transfer to the uterus. About 20% of pediatric intensive care units hospitalizations include sepsis, the most common cause of morbidity and mortality, and information from Italian pediatric intensive care units provides 50% mortality in children with septic shock. In adults, there is evidence that increased BNP is associated with heart failure (HF) and increased mortality in cases of severe sepsis and

septic shock. Sepsis is a systemic response to life-threatening infection, including symptoms of fever, increased heart (HR) rate, and increased respiratory rate (RR). The patient's life is endangered if the diagnosis is delayed. BNP is a useful diagnostic marker in patients with pulmonary hypertension. Increased BNP is associated with hemodynamic compromise, congenital heart disease (CHD), and severe clinical conditions [1-3]. The study of 73 patients by Gisela L et al. (2017) found that BNP can predict hemodynamic changes and prognosis and response to treatment in infants with septicemia [1]. The study of Wang et al. (2015) on 38 patients reported that BNP could be used as a routine hospital marker to predict sepsis in patients [2]. Astudy by Samransamruajkit et al. (2014) on 43 patients with high BNP levels, the mortality rate of children with septicemia was strongly correlated [3]. In another study conducted by Okur et al. (2019) on 87 patients and 35 controls showed that BNP has a high sensitivity (72%) and specificity (86%) for predicting sepsis [4]. According to studies of various biomarkers used to diagnose sepsis, none have sufficient predictive value to confirm or rule out sepsis. However, it has recently been hypothesized in infants that serum NT-pro BNP levels may be a good predictor of the severity of sepsis and the response rate to treatment and prognosis of these patients.

This study aimed was to investigate the relationship between serum natriuretic level of peptide type B and neonatal sepsis.

MATERIALS AND METHODS

In this case-control study, all term and preterm infants were admitted to Tabriz Children's Hospital, Tabriz – Iran, with sepsis from May 2021 to September 2021. Their septicemia diagnosis was confirmed after obtaining informed consent. According to the sample size formula [3] and placing it in the procedure related to the sample size (X = Z2 * p * (1-q)) in intervention studies with a small variable, this number has been obtained and considered as 100 patients; that neonates in the study group (Case) was 50 patients and the number of control patients (Control) was 50 patients. Neonates with cardiovascular disease (CVD), other non-cardiac conditions that involve myocardium, and neonates with pulmonary disease were excluded. Inclusion criteria were term and preterm neonates with symptoms and paraclinical signs of sepsis and approved diagnosis of sepsis by neonatal specialist.

Complete Blood Count with Differential (CBC-Diff), C-reactive protein (CRP), Blood culture (B/C), Urine culture (U/C), Urine microscopic analysis, and NT-pro BNP were checked as study nodes, and finally with laboratory results of the control group with the same number of infants who did not have clinical and laboratory symptoms of sepsis only because of high bilirubin was hospitalized and compared with phototherapy.

Criteria for diagnosing sepsis included clinical signs of seizures, fever, vomiting, anorexia, hypothermia, cyanosis, respiratory distress, and hyperreflexia.

To measure NT-pro BNP, onecc of blood was taken from the patient and examined in the laboratory by ELISA method with a Siemens kit made in Germany. Sampling was performed for Urine Analyze (U/A) and U/C after washing and drying the site using a catheter. U/A results whit white blood cells (WBCs) greater than five or Red blood cells (RBCs) greater than five and positive nitrite test or observation of bacteria and yeast if epithelial cells were low were considered active urinalysis. For CBC- diff, 2 ccs of blood were collected in an EDTA test tube and sent to the laboratory. Also, for CRP, half a cc of blood was centrifuged in the laboratory, and its serum was isolated, and then measured by ELISA (Scaleo CRP kit is made in Italy). Toperform blood culture, 2 ccs of whole blood were obtained under sterile conditions in a two-phase culture medium (Iranian manufacturing company), sent to the laboratory, and performed manually. After collecting samples, laboratory results, including serum levels of NT-pro BNP, were compared in case and control groups.

The data obtained from the study were analyzed using descriptive statistical methods (mean±SD and frequency(%)) and mean difference test for independent groups and chi-square test and analyzed using SPSS/WIN statistical software. Furthermore, statistical analysis was performed. P values less than 0.05 were considered significant.

RESULTS

Thirty-eight patients (38%) were boys, and 62 patients (62%) were girls. The mean age of the patients was 7.58±7.46 days, with a median of 4 days. The minimum age of patients was 3.5 days, and the maximum was 29 days. The mean weight of the studied patients was 2811.80±620.33 grams, with a median of 2855 grams. The minimum weight of patients was 1190 grams, and the maximum was 4400 grams. The demographic findings and clinical symptoms of patients are shown in Table 1. The most common clinical symptom observed in patients in the case group was fever (100%) followed by poor feeding (84%). In the control group, all patients had jaundice.

The laboratory findings of the studied patients by study groups are shown in Table 2. The mortality rate in the study group was 4%. Evaluation of the relationship between primary NT-pro BNP and response to treatment and survival of patients showed that NT-pro BNP levels were significantly higher in infants who did not respond to treatment and died.

Table 1: Demographic findings and clinical symptoms of patients

Variable	Case (N=50)	Control (N=50)
Demographics		
Boy	24 (48%)	14 (28%)
Girl	26 (52%)	36 (72%)
Age (days)	10.90±9.23	4.12±1.45
Weight (grams)	2644.80±598.52	2978.80±601.93
Clinical Symptoms		
Fever	50 (100%)	0
Weakness	40 (80%)	0
Shock State	12 (24%)	0
Vomiting	8 (16%)	0
Poor feeding	42 (84%)	0
Icter	0	50 (100%)

** The results are presented as mean±SD and frequency (%).*

The NT-pro BNP level cut-off point in predicting the final treatment status and mortality of neonates with sepsis was 9583 with a sensitivity of 97.7% and specificity of 93.6% (Figure 1).

Positive Urine Analysis	30 (60%)	0	-
Positive Urine Culture	0	0	-
Mortality	2 (4%)	0	0.231

** The results are presented as mean±SD and frequency (%).*

DISCUSSION

In this study, a case-control analysis was performed to evaluate the predictive value of serum natriuretic type B peptide level in neonatal sepsis. Fifty infants were also studied as a control group, 38% of whom were boys, and their mean age was 7.58±7.46 days with a median of 4 days.. Sepsis is one of the standard clinical conditions that directly and significantly affect infant mortality and morbidity. According to World health organization (WHO) estimates, sepsis accounts for about 60 to 80% of infant mortality cases per year [5]. Sepsis also accounts for nearly 20% of intensive care unit admissions and is the leading cause of mortality and morbidity in the Pediatric Intensive Care Unit (PICU). The results of the surviving sepsis campaign show mortality of 34.8%, and this number is higher in developing countries [6, 7]. Results from Italy also show a mortality rate of nearly 50% in the PICU of neonates admitted with septic shock [7]. The results show that the hospitalization rate of neonates with sepsis is higher than controls, and most studies have emphasized the importance of rapid diagnosis and treatment. A recent study reported that rapid diagnosis and intervention in infants with septic shock can be highly life-saving and that the outcome of patients can be more favorable [8]. Rapid diagnosis of sepsis and balancing hemodynamics of patients are the main factors involved in reducing patient mortality. Intravenous antibiotics are also a key to treating patients [9].

The results of the present study showed that the most common clinical symptoms in neonates with sepsis include fever (100%), weakness (80%), shock state (24%), and vomiting (16%). In the control group, all patients had jaundice. Evaluation of patients' laboratory findings showed that neonates with sepsis had significantly higher initial NT-pro BNP values than the control group (10,023.80 vs. 2,247.20; p = 0.001). Numerous biomarkers have been evaluated to evaluate the status of patients with severe sepsis and septic shock. For example, procalcitonin has recently been directly associated with the severity of bacterial infections [10]. In addition, cardiovascular disease is more common in children than in adults with severe sepsis or septic shock, so that in 58% of cases, low cardiac output with high peripheral vascular resistance, and in 22% of cases, they have low cardiac output with low peripheral vascular resistance [11,12]. Therefore, biomarkers associated with cardiovascular disorders in infants and children can benefit infants with sepsis. NT-pro BNP is a biomarker synthesized and secreted by myocytes and atrial and ventricular fibroblasts and is also associated with cardiovascular dysfunction [13,14]. As mentioned in the present study, neonates with sepsis had significantly higher serum NT-pro BNP levels than the control group. Also, after treatment, the level of this biomarker in patients in the affected group was reduced considerably (23,786.56 vs. 10,023.80; p = 0.001). Recently, researchers found that measurement of primary NT-pro BNP levels in neonates with sepsis was significantly associated with patient mortality and lays the groundwork for fluid therapy decision-making for fluid therapy. This study indicated that the volume of positive fluid balance in patients was directly related to increased serum BNP levels [15]. The above research results are consistent with our study It is better to evaluate the level of electrolyte balance in patients with sepsis and its relationship with the serum level of NT-pro BNP in future studies.

In the present study, in terms of the outcome, 96% of patients with sepsis had successful treatment, and 4% died. The results of evaluating the value of pro-BNP diagnosis in predicting the final treatment status of neonates with sepsis with a 9,583 cut-off point had a sensitivity of 97.7% and specificity of 93.6% (p = 0.002; AUC = 0.969). Similarly, a good prognosis has been reported for PICU mortality [3]. In recent years, several studies have been performed that show a significant and traceable increase in serum BNP levels in patients with sepsisthTherise in serum BNP and NT-pro BNP levels havebeen directly related to increased mortality in patients [3,16,17]. The increase in BNP is high in patients with sepsis, but ventricular dysfunction in these patients is not easily measured.

On the other hand, several factors such as lipopolysaccharides (LPS) [18], inflammatory cytokines like Tumour Necrosis Factor - alpha (TNF alpha) and interleukin-1 beta (IL-1 beta) [19], and catecholamines [20] also increase BNP. Recent studies have shown that BNP levels in neonates with sepsis caused by gram-negative bacteria were higher, indicating the effect of the type of bacterial strain, so that the bacterial polysaccharide may have led to a more severe immune response. Therefore, it is suggested to be considered in future studies [21]. In neonates with sepsis, other mediators, including endotoxins, inflammatory cytokines, and myocardial depressant factors, increase NT-pro BNP levels through myocardial damage and dysfunction [22]. Therefore, it is better to perform Doppler echocardiography in these patients to evaluate cardiac function after the initial critical procedures. In this study, negative urine culture results despite active urinalysis may be due to the early initiation of antibiotic treatment in the first venipuncture.

Limitations of study

One of the limitations of this study is the lack of data on the effect of serum bilirubin on BNP. The second limitation of this study is the lack of information on the effect of electrolytic disorders on serum BNP levels.

CONCLUSIONS

Overall, according to the results obtained in this study, it can be concluded that measuring the serum level of NT-pro BNP in neonates with sepsis at the time of observation of clinical symptoms with a sensitivity of 97.7% and specificity of 93.6% with a cut-off point of 9,583 is an important prognostic factor. In the medical management of patients. In future studies, the relationship between the type of bacterial strain leading to sepsis and the level of electrolyte balance in patients with sepsis be compared with the serum levels of NT-pro BNP and BNP.

Ethical Approve

The ethics committee approved the present study with the code (IR.TBZMED.REC.1400.141) of Tabriz University of Medical Sciences. Because all diagnostic procedures have been performed for the diagnosis and treatment of patients and in addition to the treatment process of patients, no additional blood sampling and no cost for measuring serum NT-pro BNP level wastaken from patients, so no ethical case does not exist.

Quality of life assessment for rectal cancer patients: A comparison between sphincter preservation and permanent colostomy

Masoud G. Jomehei[1], Reza R. Ravan[2], Maryam Emadzadeh[3], Majid Ansari[2], Abbas Abdollahi[2]

Abstract: *This study aims to compare the quality of life in patients with rectal cancer between sphincter preservation and permanent colostomy. The present study is a cross-sectional study that was performed on 120 patients (60 cases in the sphincter maintenance group and 60 cases in the permanent colostomy group) who underwent surgery from February 2017 to November 2016. Quality of life assessment was provided with QLQ-C30 and QLQ-CR29 questionnaires. Finally, the collected data were analyzed using SPSS23 software. According to the results of the QLQ-C30 questionnaire, there was no statistically significant difference in patients' quality of life in terms of performance in the study groups (P>0.05). Symptoms such as nausea, pain, shortness of breath, sleep disturbance, loss of appetite, constipation and economic problems in the study groups were not statistically significant (P>0.05). But the mean symptoms of fatigue (P=0.038) and diarrhea (P=0.037) were significantly higher in the sphincter maintenance group than the permanent colostomy group. The mean score of patients' quality of life was 53.43 ± 8.40 in the sphincter retention group and 52.23 ± 11.45 in the permanent colostomy group (P = 0.556). According to the results, the quality of life in the two surgical methods of sphincter preservation and permanent colostomy was not statistically significant. Therefore, treatment decisions should be made by informing patients, both based on their preferences and the physician's clinical judgment.*

Keywords: *rectal cancer, colostomy, sphincter*

INTRODUCTION

In most countries, especially developed countries, cancers are the second leading cause of death after heart disease [1]. After lung and prostate cancer, colorectal cancer (CRC) is the third most common cancer in the world and among men, and after breast cancer it is the second most common cancer among women (Figure 1) [2]. In Iran, after heart disease and accidents, cancers are the third leading cause of death [3]. In the United States, it is the fourth most common cancer in men after skin, prostate and lung cancers, and the most common cancer in women after skin, lung and breast cancers [4]. In fact, colorectal cancer is caused by the uncontrolled growth of the inner layer of the organs of the colon and rectum, which increases with age [4].

The exact cause of colorectal cancer is not known, however, the disease is not contagious and no one gets the disease from another person [5]. Research has shown that people with certain risk factors, such as aging, family history, genetic disorders, smoking, colorectal polyps, and poor diet, are more likely suffering colorectal cancer than other people [6]. The first line of treatment is surgery to remove the tumor. Surgical methods include: anterior resection with reconstructive anastomosis and tumor removal, and surgery to remove the rectum from the perineum and abdomen with a permanent ostomy [7].

In case of metastasis, supportive surgery is performed to eliminate the symptoms, prevent obstruction and improve the patient's quality of life. In some cases, an ostomy may be needed to treat cancer during bowel resection [8]. The choice of treatment is based on the staging of the disease and surgery is the basis of definitive treatment in the early stages. Today, chemotherapy and sometimes radiotherapy (in rectal cancers) are used in the form of adjuvant in certain stages of the disease [9]. An ostomy (ileostomy or colostomy) is the creation of a wall on the abdomen that is used to help the bowel or bladder drain. Depending on the type of surgery used and the extent of the disease, a colostomy may be temporary or permanent [10]. Most patients with colorectal cancer survive for at least 5 years after diagnosis, so quality of life is an important issue in these patients [11].

Understanding the quality of life experienced by patients with colorectal cancer is essential to assessing the impact of the disease on individuals, their families, and their communities [12]. Cancers can cause a change in the patient's assessment of their health and quality of life by causing physical, social, economic, and etc. disorders. Awareness of patients' quality of life can be considered as an effective factor in making clinical decisions and managing the problems of these people and can also be useful in guiding and accompanying these patients in better use of support and rehabilitation facilities [13]. Abdominal Perineal Resection (APR) surgery, which involves a permanent colostomy, is performed for patients with lower rectal cancer with sphincter involvement or those who are more likely have a malfunctioning sphincter after sphincter retention. Numerous studies have suggested that patients with colostomy experience have significant changes in various aspects of quality of life, including the physical, social, and physiological dimensions, compared with those undergoing anatomical preservation of the sphincter [14]. Therefore, in the present study, we aimed to compare the quality of life in patients with rectal cancer between sphincter preservation and permanent colostomy.

MATERIALS AND METHODS

This study is a cross-sectional study and was performed in colorectal surgery clinic or ostomy care clinic of Ghaem Hospital in Mashhad from February 2017 to November 2016. This research was presented in the organizational ethics committee of the university which was approved with the code IR.MUMS.MEDICAL.REC.1399.457. Inclusion criterias were patients over 18 years of age who presented for follow-up after previous treatment for rectal cancer, including radical surgery with Total Mesorectal Excision (TME), in the colorectal ward of Ghaem Hospital with or without sphincter retention. At least 12 months after APR or aberrant ostomy closure, if they agreed to participate in the study, they entered the project. Exclusion criterias were patients with ostomy with a different histology from adenocarcinoma and intraperitoneal rectal tumor, patients with peritoneal carcinomatosis, and patients who had not received neoadjuvant before surgery were excluded from the study. Patients were divided into two groups: 1) the sphincter retention group (SPG), which included patients who underwent a lower colorectal or coloanal anastomosis; And 2) permanent colostomy (OCG) group, which included patients who underwent permanent APR and terminal colostomy. In this study, 120 patients (60 cases in the sphincter maintenance group and 60 cases in the permanent colostomy group) were included in the study.

QLQ-C30 Questionnaire

A multidimensional questionnaire consisting of 30 questions that quality of life in 5 functional areas (physical function, role-playing, emotional, cognitive and social) and 9 areas of symptoms (fatigue, pain, nausea, vomiting, shortness of breath, diarrhea, constipation examines, sleep deprivation, loss of appetite, and economic problems caused by illness) and one general area of quality of life.

QLQ-CR29 Questionnaire

This questionnaire is designed to assess the quality of life of patients with colorectal cancer and includes 29 questions that describe the symptoms (gastrointestinal, urinary and pain symptoms) and functional status (such as sexual function and body image) of patients with colorectal cancer. This questionnaire has a separate questionnaire to measure the sexual function of men and women.

Quality of life assessment

Quality of life assessment was performed with QLQ-C30 and QLQ-CR29 questionnaires. In this way, patients were informed about the design and nature of the questionnaires; They filled out the questionnaires independently and if they had any problems, they were given a proper explanation by the project implementers.

Statistical Analysis

After completing the checklists, the information was analyzed by entering it in SPSS23 software. Data description was expressed with tables and graphs and central indicators and dispersion. Mann-Whitney test was used to compare quantitative data between the two groups due to abnormal data distribution. Chi-square test was used to compare qualitative data between the two groups. Significance level in the tests was considered P>0.05.

RESULTS

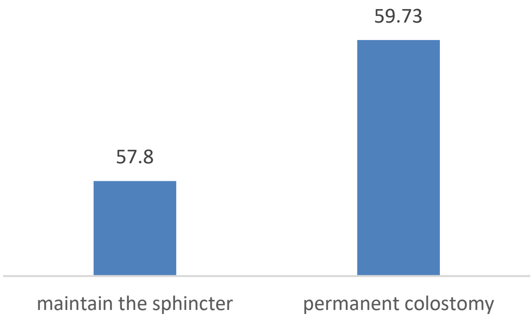
Average age of patients

The mean age of patients in the sphincter maintenance group was 57.80 ± 9.96 years and in the permanent colostomy group was 59.73 ± 9.31 years (P=0.196) (Figure 2).

Gender of patients

60% of the participants in this study were male and 40% were female. The frequency of patients related to gender in each of the study groups can be seen in Table 1. The results of Chi-square test showed that the sex of patients in the study groups was not meaninful (P=0.456).

Figure 2: Mean age of patients in the studied groups



Other variables

The results of Chi-square test showed that marital status (P=0.283), level of education (P=0.6), place of residence (P=0.224) and family history of colorectal cancer (P=0.409) were not significant in the study groups (Table 2).

Quality of Life Assessment Questionnaire for cancer patients (QLQ-C30 Questionnaire)

According to the results of QLQ-C30 questionnaire in Table 3, patients' quality of life in the field of performance including physical function (P=0.103), role playing (P=0.162), emotional (P=0.050), cognitive (P=0.801) and social (P=0.713) There was no significant difference in the study groups. Symptoms include nausea (P=0.535), pain (P=0.298), shortness of breath (P=0.513), sleep disturbance (P=0.231), loss of appetite (P=0.3609), constipation (P=0.303), and economic problems (P= 0.584) in the study groups were not meaninful. But the mean symptoms of fatigue (P=0.038) and diarrhea (P=0.037) were significantly higher in the sphincter retention group than the permanent colostomy group. The mean score of patients' quality of life was 53.43 ± 8.40 in the sphincter retention group and 52.23 ±11.45 in the permanent colostomy group. The results of Mann-Whitney test showed that the quality of life of patients based on the QLQ-C30 questionnaire in the study groups was not significant (P=0.556).

According to the results of the QLQ-C29 questionnaire in Table 4, the quality of life of patients in the areas of functions including anxiety (P=0.171) and female sexual function (P=0.0725) in the study groups were not significantly different. But the quality of life of patients in the areas of functions such as body image (P=0.021), weight (P=0.032) and male sexual function (P= 0.016) in the sphincter maintenance group was significantly higher than the permanent colostomy group. There were no significant differences in the mean symptoms such as hip pain (P= 0.125), hair loss (P = 0.265), taste disturbance (P=0.070) and skin ulcers (P= 0.100). But the mean of symptoms such as frequent urination (P =0.018), blood in the stool (P = 0.013), stool frequency (P=0.044), urinary incontinence (P=0.01), heartburn (P= 0.01), abdominal pain (P=0.01), bloating (P=0.01), dry mouth (P=0.01), excessive bowel movements (P= 0.01), fecal incontinence (P= 0.01), and embarrassment sense (P=0.01), impaired. There was a meaningful difference between erection (P=0.01) and dyspareunia (P=0.001) in the study groups.

DISCUSSION

Annual colorectal cancer, with nearly one million new cases and the death of about 50% of patients in the first five years of disease onset, is a major public health problem of worldwide [15]. This is necessary to study the quality of life in patients with CRC. However, according to some reports, the cases of CRC in our society are younger than the cases in developed societies [16]. This indicates the patient's level of involvement in the disease in terms of working age, and social activities. The mean age of patients in our study is 58.76 ± 9.65 years old, although the mean age of colorectal cancer patients has been reported differently in several studies [17, 18]. The results of our study demonestrated a higher prevalence of the disease among men (60%). Previous studies have shown that the disease is more common in men than women and occurs more at older ages [19, 20]. Studies in Australia, Italy, and the United Kingdom have found that men are more prevalent than women, but American studies have shown that the prevalence is equal in both sexes [17, 21]. The above comparison indicates that the prevalence rates of sex as well as age of disease onset vary in different societies. In our study, most of the patients lived in the city (71.7%). A study in China noted a very rapid and significant increase in the incidence of colorectal cancer in Shanghai, the most industrial city in China, showing a relationship between the incidence of colorectal cancer and industrial life [22]. The results of our study showed no significant difference in the quality-of-life score between the two methods of sphincter maintenance and permanent colostomy. To confirm our results, we can refer to the cross-sectional cohort study conducted by Trenti et al. 2018, noted that 385 patients with middle and lower rectal cancer underwent APR, cancer risk assessment (CRA) and colon anastomosis (CAA) were compared. The results showed that the quality of life of the patients was generally similar in the 3 groups [23]. In 2012, How et al. compared 32 patients with low anterior resection (LAR) and 30 patients with APR in the United Kingdom, and concluded that the APR method was not necessarily associated with a lower quality of life than LAR [24]. Another study conducted by Mariand Sias et al. in the colorectal tumor department of the Camargo Cancer Center in Brazil, they compared 83 patients who underwent inferior or coloanal anastomosis and 42 patients who underwent APR. Quality of life scores did not differ between the two groups, but patients who underwent permanent colostomy had significantly better scores in terms of function and symptoms [25]. In addition, at the University of Aldomord in Italy, Dignar et al. examined 26 patients who underwent APR and 34 patients who underwent CAA colloidal anastomosis, and the quality of life in patients with permanent ostomy compared to patients who underwent CAA. There was no significant difference. However, APR patients had poorer sexual function, while most CAA patients had fecal incontinence [26]. The results of their study are consistent with the results of our study in terms of no significant difference in quality of life between the two groups, but in our study, fecal incontinence as well as male sexual function in patients in sphincter maintenance surgery group compared to patients in permanent colostomy group was better evaluated. The reasons for this discrepancy are the low sample size in these studies and the demographic and age differences between patients in the two studies. Recent study, disclosed differences in quality of life between patients with sexual dysfunction and patients without sexual dysfunction. Sexual dysfunction may be due to pelvic nerve damage or, indirectly, to vascular injury produced by radiotherapy or surgery. In addition, psychological factors can affect these disorders [27, 28]. Similarly, it has been demonstrated that women's sexual function and sexual arousal ability are complex and can easily be affected by factors such as pain [28]. In our study, patients' sexual performance in both men and women after permanent colostomy was worse than sphincter preservation surgery, but this difference was not\significant in women. Based on a review study by Fernández-Martínez et al. loss of normal rectal function, urinary problems, sexual dysfunction, or pelvic pain are frequently reported in patients after rectal surgery, and these abnormalities significantly affect the quality of life [29].

CONCLUSIONS

According to the results of our study and the findings of other studies, the general conclusion that can be drawn from this study is that the quality of life in the two methods of sphincter maintenance surgery and permanent colostomy was not statistically significant. Therefore, treatment decisions should be made by informing patients, both based on their preferences and the physician's clinical judgment, to ensure that patients enjoy an optimal quality of life after treatment. However, due to study limitations (sample size and short-term follow-up), longer follow-up studies with more patients are needed.

Retinal migraine, a contentious clinical entity

Carmen A.Sirbu[1], Vera M. Nicolescu[1], Ana O. Nițiș[1], Raluca S. Costache[2], Constantin Ștefani[3], Marian Mitrică[4], Dragoș C. Luncă[5], Daniela Anghel[6]

Abstract: *Retinal migraine (ophthalmic migraine, ocular migraine, anterior visual pathway migraine) is a rarely encountered medical condition, but with an interesting and complex clinical presentation. The goal of this article is to compile the literature on retinal migraine, detailing nomenclature, pathophysiology, differential diagnosis, and medical investigations including newer imaging modalities, like optical coherence tomography (OCT). We will approach topics of great concern such as risk factors, complications, treatment, and management of this condition. Retinal migraine is mainly a diagnosis of exclusion and it must be isolated from transient monocular vision loss (TMVL) developed from other causes, for instance, papilledema, giant cell arteritis, carotid artery disease (amaurosis fugax), intermittent angle closure glaucoma, and others. Its treatment is similar to migraine treatment; topiramate, amitriptyline, and nortriptyline are some of the pharmacological drugs successfully used.*

Keywords: *ocular migraine, arterial vasospasm, retinal migraine, monocular vision loss, visual phenomena, ophthalmic migraine, anterior visual pathway migraine, scotoma, scintillation, headache*

INTRODUCTION

Retinal migraine is a debatable disorder, that was firstly introduced by Galezowski in 1882 who used the term ‘‘ophthalmic megrim’’ to describe a permanent unilateral loss of vision associated with headache [1]. The official term, “retinal migraine” was introduced in 1970 by Carroll [2] and the authors have used it to describe a multitude of monocular visual symptoms, including events without the associated headache and those resulting in persistent visual loss. The evolution of terminology accepts retinal migraine, ophthalmic migraine, ocular migraine, and anterior visual pathway migraine, as the same notion, but all of these should not be confused with ophthalmoplegic migraine, which is manifest by ophthalmoplegia and unilateral headache [3].

The International Classification of Headache Disorders (ICHD) published 1988 an international definition for this condition [4] and following the 2018 ICHD-3 updates, ocular migraine is defined as fully reversible and repeated attacks of unilateral visual manifestations, such as scotoma, scintillation, or even blindness, associated with headache [5].

Furthermore, because it is not a common entity and there are many other potential causes of monocular visual loss, retinal migraine is considered a diagnosis of exclusion [6] and a careful evaluation is needed because it can share characteristics with migraine with aura and acephalgic migraine, which can create confusion in their differentiation [7]. In some articles was also suggested the term “migraine associated with monocular visual symptoms” was to differentiate it between the loss of vision in one hemifield and that of one eye which includes sites other than the

retina, such as the choroid or the optic nerve [8].

RETINAL MIGRAINE-WERE WE ARE?

Epidemiology

The lack of reported cases, the paucity of existing literature, and the continuously evolving diagnostic criteria made the understanding of this condition's epidemiology challenging, moreover, some authors suggested that there's no epidemiologic data specific to ocular migraine [7]. While migraine is a common disorder, with a prevalence of 18.2% in female patients and 6.5% in male patients, with a higher prevalence in whites (20%) than blacks (16%) and Asian Americans (9%) [9], there were indicated only 12 cases of retinal migraine, that followed the ICHD diagnosis criteria in the last 15 years [6], between 2006 and 2020. Of 12 patients, 10 were women with an average age of 39.5 years, 11 out of 12 had a previous history of migraine headaches, 4 patients reported a history of migraine with aura and a positive family history of migraine was present in 4 of the 8 patients for which that information is available [6].

Even though based on the statistics, retinal migraine tends to affect women more so than men [6] and begins in the second to third decades, with peak prevalence in the fourth and fifth decades [10], it can also affect children, in which 7% of migraines are thought to be ocular [11] and the onset of ocular migraine may occur as late as the fifth decade, including patients with no previous history of migraine [12]. It is crucial for this last age group (>50 years of age) to consider retinal migraine a diagnosis of exclusion and make a careful cardiac and carotid evaluation, because atherosclerosis, collagen vascular disease, and hypercoagulable states are just a few examples of diseases that can explain the visual disturbances on elderly patients. A genetic predisposition is suggested by the strong family history of ocular migraine, but no clear inheritance patterns have been delineated, however, 50% of patients have a family history of some type of migraine [13,14]. In patients with familial hemiplegic migraine have been found calcium channel mutations such as 19p13 CACNA1A, ATP1A2, SCN1A, mutation appeared in siblings with migraine with aura at a statistically significant occurrence [15]. Moreover, some patients, during and between migraine episodes have been shown high levels of endothelin-1, a potent vasoconstrictor peptide, which in these cases, had significant polymorphism for a receptor found to mediate vasoconstriction [16]. However, its effect on ocular migraine is considered to be minimal because the blood-brain barrier prevents endothelin entry into the retinal circulation [7]. Finally, it is considered that retinal migraine is a less benign disorder than migraine with aura due to the higher risk for patients with transient monocular visual loss to develop permanent monocular visual loss [8].

Pathophysiology

Despite that multiple theories have been proposed, the pathophysiology of ocular migraine remains controversial because this complex disorder which associates headache and monocular visual disturbances is not fully understood. In first, the cephalgia that also appears in common migraine and in migraine with aura, is considered as trigeminal nerve activation by an unknown trigger [17]. Even if, in migraine patients, the trigeminal nerve seems to produce higher levels of glutamate onto the circle of Willis, the primary event remains unclear [18]. It is also suggested that the potential cause of inflammation and pain may be represented by a series of substances and peptides, such as bradykinin, substance P, calcitonin gene-related peptide (CGRP), and nitric oxide [19]. Secondly, to explain the monocular visual loss, we will mention the vasospastic theory that was firstly introduced by Carroll in 1970 when he exposed the hypothesis that the mechanism of visual symptoms is due to "paroxysmal constriction or spasm in either the central retinal artery or ophthalmic artery" [2]. It seems that serotonin and stimuli such as food may induce the production of prostaglandin, causing disturbance of cerebral autoregulation and platelet aggregation [20]. Once axons are excited, neurogenic and vascular inflammation (especially the inflammation of the retinal and ophthalmic vessels) may cause vasospasm, obstruction, and ocular sympathetic dysfunction which can explain the visual symptoms [7]. Serotonin may have a major role in ocular migraine because it has been measured that it is produced by platelets in increased levels in aura phases of migraine, mediating intracranial vasoconstriction [21], and, furthermore, in patients with atherosclerosis, it reduces blood flow to the choroid and retina while the intracranial blood flow is not significantly affected [22]. However, other authors consider that the vascular theory is nowadays largely rejected by new cerebral blood flow imaging techniques [23] and it is indicated a series of potential mechanisms including cortical spreading depolarization, brainstem and hypothalamic activation, alteration in thalamo-cortical circuits or neuropeptide production (pituitary adenylate cyclase activating polypeptide and calcitonin gene-related peptide) [24]. None of these new hypotheses is confirmed. The last theory, cortical spreading depression (CSD) of retinal neurons, is indicated by several articles as a plausible explanation, but it hasn't been demonstrated in vivo or in any animal with retinal vasculature. The phenomenon can be exposed as an "excitation wave followed by depression of neuronal activity propagating through gray matter with a velocity of approximately 3 mm/min" [25], as it is described by Leao in 1944. Based on magneto-encephalographic studies, CSD is suggested to be the biological explanation for the occipital aura that affects both eyes and precedes headache in migraine with aura patients [26]. Retinal SD has only been studied on chick or frog retina, and never been demonstrated in mammals, furthermore, the isolated retina in animal experiments is not representative of the human eye in vivo, which is vascularized and supported by the vascular choroid [27].

Clinical presentation

According to literature, where has been reported a limited number of cases of retinal migraine that followed ICHD diagnosis criteria, the patients, which are usually females, in the second to third decade of life, with family history of migraine and previous history of migraine with aura, present to the specialist with unilateral visual loss that can last even few seconds or between 5 to 30 minutes, and can be preceded, accompanied or followed by ipsilateral headache [6]. The visual disturbances include positive or negative phenomena that are fully reversible, but a majority of patients (>70%) has repeated attacks [13]. There have been described positive phenomena such as zigzag lightning, diagonal lines, halos, and scintillation [7], while the negative ones are described by the patients as black dots or spots, blurring, blank areas, and complex patterns are less common [8]. It is also considered that benign episodic pupillary dilation, an under-reported ophthalmologic sign, might be connected with ocular migraine [7]. All these monocular visual symptoms can be caused by any process that affects the optic nerve or the ocular blood flow and therefore a normal neuro-ophthalmic exam is crucial to exclude any other causes of transient monocular visual loss [28]. The majority of the patients has a good prognosis with a full recovery and permanent visual loss is uncommon.

Differential diagnosis

The diagnosis of retinal migraine is by exclusion [29]. The patients accusing transient monocular vision loss (TMVL), who fits the criteria for retinal migraine according to ICHD-3 must undergo a series of further investigations in order to exclude alternative diagnoses such as: vascular disease, ocular disease or optic nerve disorders. ICHD-3 criteria require positive and/or negative visual phenomena. These are monocular, fully reversible and are confirmed by clinical visual field examination and the patient's drawing of a monocular field defect. Additionally, it should meet two out of three criteria of the following: spreading gradually over 5 minutes or more; symptoms lasting between 5 and 60 minutes; headache present simultaneously, or following the sympyoms within 60 minutes. Vascular diseases that mimic TMVL are carotid artery disease, central retinal artery occlusion, giant cell arteritis (affects large and medium sized arteries), choroidal ischemia (originating from posterior ciliary arteries or arteritis processes affecting the short posterior ciliary arteries). There are some conditions affecting the optic nerve that must be taken into consideration, for example, Uhtoff's phenomenon (can be induced by exercise) from demyelinating disease, papilledema, and compression of the optic nerve [30]. Amaurosis fugax appears as a result of the stenosis or occlusion of the internal carotid artery (caused by hypoperfusion from the stenosis or thromboembolism from the carotid circulation) [31]. Interrupted circulation to the ophthalmic artery or central retinal artery can manifest through a blackout in the entire or only half of the visual field. Patients can accuse a "curtain sweeping in from one side of the vision" and it usually takes between a few minutes and an hour [30]. Amaurosis lasting seconds is commonly found in disc edema (papiloedema), whereas painless amaurosis lasting less than 15 minutes occurs typically from an embolic source (cholesterol, platelets, calcium). Furthermore, dry eyes and intermittent angle closure glaucoma needs to be excluded since they are causes of TMVL as well [30]. To differentiate retinal migraine from other types of visual loss it is important to establish if the issue affects one or both eyes and to define whether the visual loss is monocular or in one hemifield. If the problem is binocular, it is likely a retrochiasmatic injury. In contrast, if the loss of vision concerns one eye it can be as a result of prechiasmatic lesions. It can be problematic for patients to recognize hemianopias from monocular vision loss, therefore the physician needs to guide them in this regard.

Investigations

The evaluation of a patient with acute monocular vision loss begins with a thoroughly medical history. Data including patient's age, history of vascular risk factors, cancer, autoimmune diseases is essential in establishing a proper differential diagnosis. Crucial information regarding the episode of vision loss is frequency, characteristics and duration [30]. It is important to check if the patient has a positive medical history for other types of migraine and if exercises precipitate the attacks [32]. Patients must complete formal visual field assessments in search of visual field defects [6] including negative symptoms, for instance, altitudinal vision loss, central scotoma and sectorial loss [30]. Other visual manifestations that may appear are positive symptoms like scintillations, flashes of color, light, stars, and heat waves [7]. A detailed retinal examination following pharmacologic pupillary dilation should be done, because information regarding the appearance of the retina and optic disc are fundamental to make an accurate diagnosis [33]. Retinal arterioles can be constricted and the fovea may become more distinct with surrounding macular retinal pallor. The optic disc may be pale early and hyperaemic later. Nerve fibre bundle defect can sometimes be a late finding [34]. Newer imaging modalities, such as optical coherence tomography (OCT), a non-invasive imaging test that uses light waves to take cross-section pictures of your retina may be helpful [30]. Ophthalmological examination is expected to be normal outside of attacks. Besides echocardiogram and auscultation of carotid arteries and heart, carotid Doppler is required to exclude vasculo-oclusive diseases [30], a Holter monitor if an arrhythmia is suspected [29] and transesophageal echocardiography to check all the valves and chambers in more detail [7]. Laboratory evaluation is required for diagnostic possibilities such as giant cell arteritis, collagen vascular disease, hypercoagulable states, vasculitis, and illicit drug use. Neuroimaging can exclude an orbital or intracranial mass [6].

Complications

Although it is uncommon [7], some of the complications of retinal migraine can lead to permanent loss of vision [35]. Complications reported in the literature include: “reversible and irreversible central retinal artery occlusion (CRAO), branch retinal artery occlusion (BRAO), retinal infarction” [36], retinal hemorrhages, vitreous hemorrhage, ischemia of choroid or optic nerve [35] dilatation of retinal veins and retinal pigmentary changes [3]. Optic nerve drusen are refractive, calcified nodules located within the optic disc [37]. They make the retinal vasculature more vulnerable to ischemia and lead to irreversible BRAO [38].

Risk factors

Similar to migraine, risk factors for retinal migraine are represented by stress, smoking, hypertension, and contraceptive pills. It can also be precipitated by exercise, bending over, high altitude, dehydration, hypoglycemia and excessive heat load, although dietary factors (caffeine, alcohol, tyramine, monosodium glutamate, and aspartame), traumas and hypoglycemic factors are not as influential [39]. Vascular instability plays a significant role in the pathogenesis of ocular migraine. This stands out through the co-occurrence of retinal migraine and vascular diseases such as Prinzmetal’s angina and Reynaud’s phenomenon. Moreover, it is documented that the comorbidity with lupus, sickle cell disease and atheromatous disease increases the risk of developing retinal migraine [35]. The risk for stoke in patients with atherosclerosis is 1% at 1 year; whereas patients with stenosis of internal carotid artery presents a risk of 16% of ipsilateral stroke after 3 years [40].

Prophylactic treatment

In the first place, it is essential to keep under control stress factors, hypertension and to reduce, or even quit smoking. Patients should avoid triggers like hormonal contraceptive pills or exercises (if they induce amaurosis). It helps if the patients keep a diary in order to keep track of all the factors who lead to an attack, in this way it is easier to avoid them. Pharmacological treatment is required if the life style changes are not effective. Prophylactic therapy consists in calcium channel blockers (nifedipine, verapamil), nonsteroidal anti-inflammatory drugs (aspirin, dipyridamole and sulfinpyrazone if aspirin intolerant), anticoagulants (coumadin, heparin), antiepileptics (divalproex sodium/ sodium valproate, gabapentin, topiramate), antidepressants (tricyclics- amitriptyline, nortriptyline, imipramine; selective serotonin reuptake inhibitors) [7,35]. Although nifedipine, and especially verapamil are the most effective drugs in this case, there are some contraindications to calcium channel blockers including congestive heart failure, hypotension, sick sinus syndrome, cardiac conductive defects, concomitant, and renal or hepatic failure [35]. Aspirin is used for its antiplatelet activity [8] and, along with nifedipine, it is used to prevent exercise induced retinal migraine [12]. Topiramate, amitriptyline, and nortriptyline are some agents used in classical migraine that have been demonstrated effective in retinal migraine as well [6]. It is usually recommended to avoid beta blockers in ocular migraine due to its properties of arteriolar constriction [31].

Abortive treatment

It is important to avoid medication overuse by matching treatment to patient needs. Given the unsufficient number of studied cases in literature, treatment options for ophthalmic migraine are limited. According to some authors, it is enough to manage the manifestations of retinal migraine by observations alone [41,42]. Due to the short duration of the attack, abortive treatment is uncommon and the main focus of treatment should be to reduce the recurrence of attacks [35]. Regarding management, triptans and calcium channel blockers can be used as abortive pharmacological treatment. Triptans are more effective on migraine without aura, but may be successful for patients in whom other therapies do not work and who have no other risk factors for ischemic heart disease or stroke [7].

Calcium channel blockers were demonstrated effective in both prophylactic and abortive situations [43]. There have been reported two cases in literature that advocated the use of sublingual nifedipine (10 mg) for treating attacks (both patients diagnosed with systemic lupus erythematosus) [44]. During attacks, inhaled amyl nitrate and isoproterenol showed “good efficacy”, while inhaled carbon dioxide improved vision ‘slightly’ in one patient [45]. Successful treatment has been reported for coumadin and heparin used in isolated cases of patients with antiphospholipid antibody syndrome and retinal migraine [35,46]. Other medications such acetazolamide (500 mg) and sublingual nitroglycerine (0.8 mg) were effective [47]. Systemic corticoid therapy was successfully used in patients with systemic lupus erythematosus [48].

CONCLUSIONS

Retinal migraine is a rare, but increasingly recognized clinical condition. The pathophysiological mechanisms are still unclear. It is a cause of TMVL and uncommon, during prolonged periods of hypoxia, it can lead to permanent loss of vision. Retinal infarction is more susceptible in patients with anomalous optic discs or intrapapillary drusen may render the patient more susceptible to retinal infarction Researches show that retinal migraine may successfully respond to usual migraine prophylactic medications, but a current guideline is missing. It is also important to attempt to change the lifestyle factors that precipitate this condition, before initiating medical treatment. Its prognosis is a good one overall. Unfortunately, there is not enough research in this distinct clinical entity, hence, it is difficult to determine an optimal treatment regimen.

REVIEW

Analysis of neuroprotective medication in patients with neurocognitive disorders: The efficacy and tolerability of highly purified animal tissues extracts

Octavian Vasiliu[1]

Abstract: *Neurocognitive disorders are extremely invalidating psychiatric disorders with chronic courses and significant negative impacts over all areas of cognitive functioning and behavioral activity. Although extensive research on these progressive neurodegenerative disorders has been conducted, pathogenetic treatments with long-term significant benefits are yet controversial. From a clinical perspective, there is an acute need to find therapeutic strategies that could delay cognitive impairment in patients diagnosed with Alzheimer's disease (AD), vascular dementia (VaD), Lewy body dementia (LBD), etc. Also, slowing the transition from mild cognitive impairment (MCI) to clinically significant AD is another important clinical aspect, with a major impact on the patient's daily functioning, quality of life, and caregivers' burden. Acetylcholinesterase inhibitors (AChEI) are still the first line of treatment in AD patients, and they are also administered in the case of VaD or Parkinson's dementia. Various nootropics have been studied in this population, as add-on agents. Highly purified animal tissue extracts (HPATE) are administered in patients with neurocognitive disorders due to their neurotrophic properties, but many questions remain unanswered regarding their pharmacodynamic characteristics. These extracts may be added to AChEI to enhance their pro-cognitive effect, but evidence to support the superior efficacy of this association versus AChEI monotherapy is mainly derived from low-to-medium quality clinical trials. In conclusion, HPATE may be a useful add-on to first-line pro-cognitive agents in AD and VaD, but larger trials with better methodology are needed. In particular cases, however, HPATE may be of significant interest for patients with mild-to-moderate AD, based on results from clinical practice.*

Keywords: *Alzheimer's disease, vascular dementia, ischemic stroke, Actovegin, Cerebrolysin, neurotrophic factors*

INTRODUCTION

Neurocognitive disorders are associated with significant impairment in daily functioning and a high degree of depression, anxiety, and negative symptoms, which decrease, even more, the overall level of functioning in these patients [1,2]. The management of the neurocognitive disorder and associated non-cognitive symptoms is a challenge for clinicians and caregivers, due to the relatively low number of available, evidence-based, efficient pharmacological agents [3-5]. Also, special care should be taken concerning adverse events in a population with possible organic comorbidities and multiple concomitant medications [3]. Another important aspect in this population is the low overall efficacy of acetylcholinesterase inhibitors (AChEIs), which may not even be clinically significant in long term [6,7]. Still, the differences in the effect of individual AChEIs over cognitive functioning might be significant, and these differences may be modulated by yet insufficiently described patients' characteristics [6,7].

Highly purified animal tissue extracts (HPATE), based on neurotrophic factors or blood components, are used to treat the consequences of acute cerebrovascular events or traumatic brain injury, but also for the therapeutic management of neurodegenerative disorders [8-10]. The prophylactic properties of such products in the domain of brain circulatory and trophic diseases, but also for peripheral vessels diseases, allow these products to be recommended for yet another indication, e.g. Actovegin is approved to be used for skin grafts, bedsores, skin burns, etc [10]. Several HPATE are currently marketed, but the most extensively

researched agents for neurocognitive disorders treatment are Cerebrolysin and Actovegin. Although HPATE is not widely recognized as an efficient therapeutic intervention for dementias, multiple trials (reviewed below) support their efficacy in patients with mild cognitive impairment or clinically manifest dementia. Treatment with neurotrophic agents might enhance the effects of AChEIs, which are considered the first-line treatment for Alzheimer's disease (AD) [11].

In a comparative analysis of Cerebrolysin (1 or 3 mg/kg/day), Actovegin (200 mg/kg/day), and Cortexin (538 or 1614 mg/kg/day) in rodent models of acute and chronic brain ischemia, these agents were administered for 10 days [8]. Cortexin, Cerebrolysin, and Actovegin may be efficient in improving the recovery of neurological functions, by decreasing the severity of sensorimotor and cognitive impairments in preclinical models of brain ischemia [8].

OBJECTIVE

The main objective of this paper was to explore the available data in the literature regarding the efficacy and tolerability of Cerebrolysin and Actovegin in patients with neurocognitive disorders, mainly AD and vascular dementia (VaD). An inclusion criterion for the trials in this review was the existence of a structured approach for the monitoring of HPATE efficacy and/or tolerability.

The secondary objective of this review was the collection of data about the possible mechanisms of action of HPATE, based on preclinical models of AD, VaD, or acute cerebral ischemia.

Augmenting the effects of AChEIs with neurotrophic agents is frequently tried in clinical practice, because of their long-term potentially synergistic effects in the treatment of neurocognitive disorders. Therefore, illustrating the clinical use of these two products in a case series was yet another objective of this paper.

METHODS

A literature review was performed, using the search paradigm "Cerebrolysin" OR "Actovegin" OR "neuroprotective medication" AND "Alzheimer's disease" OR "Alzheimer dementia" OR "vascular dementia" OR "neurocognitive disorders". All papers published between January 1982 and February 2022 were included in the primary search. The databases included in this search were PubMed, Cochrane, Web of Science, EMBASE, and CINAHL.

A case series was presented in the second part of this article as a way to illustrate the possible pragmatic, clinical impact of HPATE on the evolution and prognosis of patients diagnosed with AD. These patients were randomly selected from our Psychiatry department database, and their evolution under treatment was described based on their chart review and post-discharge monitoring visits data.

RESULTS OF THE LITERATURE REVIEW

Some 145 papers were found during the primary search and 13 remained after de-duplication, elimination of papers which does not correspond to the main objective of this review, and of papers with insufficient accuracy of the methodology applied (i.e., not using validated instruments for efficacy monitoring, not specifying main outcomes or heterogenous population included form the principal diagnosis perspective). Five papers refer to the efficacy and/or tolerability of Actovegin in post-stroke cognitive impairment, AD, or organic brain syndrome, while 8 papers included data about Cerebrolysin effects in patients with AD, mild cognitive impairment, or VaD [11-21]. Out of these 13 papers, 12 included clinical trials, and one was a review.

Regarding the secondary objective of this review, 3 papers were found, one review (Actovegin), one animal study, and one in-vitro study (Cerebrolysin) [22-24].

Actovegin is a biological drug manufactured by ultrafiltration from calf blood, and the result is a deproteinated, pyrogen- and antigen-free hemodialysate [25]. The final product contains a mixture of natural substances, over 200 bioactive constituents with low molecular weight, both inorganic- e.g., blood electrolytes, and organic components- e.g., amino acids, oligopeptides, nucleosides, etc. [25,26]. Actovegin presents complex pharmacodynamics properties, as it may target the enhancement of cellular metabolism, with increased oxygen uptake and utilization, as well as glucose uptake in the cells [25]. This enhancement derives from an insulin-like activity mediated by inositol-phospho-oligosaccharides, therefore Actovegin is recommended for cerebral blood circulation dysfunctions and trophic disturbances, impairments of peripheral blood circulation and associated diseases, dermal transplants, and acute chronic wounds [25]. Actovegin also promotes oxidative metabolism and shifts the redox-balance of the cells into the direction of oxidized substrates, increasing the availability of energy-rich phosphates like ATP and creatine phosphate [25]. Preclinical data support a positive influence of Actovegin on the NF-κB pathway, but many molecular and cellular pathways remain unexplored [26].

According to a systematic review of Actovegin in ischemic stroke (n=5 articles), this drug acts over ischemic stroke lesions ensemble, issue oxidation, energy metabolism, and glucose availability through their augmentation, mitigation of the ischemic process and oxidative stress, and decreasing of inflammation and apoptosis-like processes [22]. Actovegin has anti-apoptotic effects by reducing the caspase-3 activation induced by amyloid β-peptides [22].

Actovegin has been used in clinical practice for more than six decades for various indications, and its safety and tolerability profile is considered very well [27]. Its clinical efficacy and favorable tolerability profile were proven in patients diagnosed with mixed dementia [14,27]. Patients aged 50-85, diagnosed with mild-to-moderate degenerative dementia or multi-infarct dementia received either Actovegin 250 ml 20% i.v. or a placebo for 4 weeks [14]. Actovegin had a significantly superior efficacy vs. placebo, according to the Clinical Global Impression (CGI) and Syndrome Short Test (SKT)- improvements with 32% vs. 4% (active drug vs. placebo) and -2.8 vs. -0.4 (active drug vs. placebo), respectively [14].

The efficacy of Actovegin in patients with poststroke cognitive impairment was evaluated in a 12-month, parallel-group, randomized, multicenter, double-blind, placebo-controlled study, which included patients ≥60 years old with a Montreal Cognitive Assessment test ≤25 points [12]. Actovegin was administered as 2000 mg/day for ≤20 intravenous infusions followed by 1200 mg/day orally or placebo for 6 months, in 503 patients [12]. The least squares mean change from baseline to month 6 in Alzheimer's Disease Assessment Scale- cognitive subscale (ADAS-Cog), extended version, was -6.8 for Actovegin vs. -4.6 for placebo, a significant difference [12]. The most frequently reported serious adverse event was a recurrent ischemic stroke, but without differences between active drug and placebo [12].

A double-blind, randomized clinical trial had as its main objective to compare the therapeutic effects of Actovegin vs. placebo in elderly patients with organic brain syndrome (N=60) [13]. Actovegin was administered as daily infusions of 250 ml 20% in 40 geriatric patients, and 20 patients received 250 ml 0.9% saline solution as a placebo, for 4 weeks [13]. These patients were diagnosed with simple dementia (58%) or senile dementia with depressive or paranoid symptoms (ICD-9) [13]. The mean Sandoz Clinical Assessment Geriatric Scale (SCAG) score in the drug group decreased from 56.3 at baseline to 36.3 points at the last trial visit in the Actovegin group, and from 61.2 to 52.0 ($p<0.01$) in the placebo group [13]. On the CGI, Actovegin administration led to "distinct improvement" or "improvement" in 70% of cases vs. only 35% in the placebo group [13]. SKT and subscales of SCAG scores supported the superior effects of Actovegin compared to the placebo, as did social behavior measurements [13].

A group of 43 patients with mild-moderate ischemic stroke received either Actovegin (N=32) or piracetam (N=11) and the analysis of their neuropsychological performances showed positive effects of the active drug over general cerebral and focal neurological symptoms after 30 days [15]. By the end of the study, the extent of recovery of impaired functions, assessed in terms of total ischemic points and cognitive functions, was significantly greater in patients treated with Actovegin than in those given piracetam [15]. Another study (N=104 patients with acute carotid ischemic stroke) evaluated comparatively the efficacy of (1) basic and reperfusion therapy without any cytoprotection, (2) citicoline 1000 mg/day, and (3) Actovegin 250 ml/day [16]. A significant decrease in neurological deficit and improvement of functional recovery was reported in patients treated both with citicoline and Actovegin on the 30th day vs. the control group [16].

In conclusion, the effect of Actovegin on cognitive function (either post-stroke cognitive impairment or AD) was evaluated in only two placebo-controlled trials and one piracetam-controlled trial [12,13,15], which included 606 patients. These trials used different scales for the quantification of the active drug's efficacy, but the results were favorable and the overall tolerability was good.

Cerebrolysin is a neuropeptide product mimicking the pharmacodynamics action of endogenous neurotrophic factors, and its positive effects on β-amyloid and τ-related pathologies have been demonstrated in experimental conditions [28]. It exerts nerve growth factor (NGF)-like activity on neurons and increases levels of NGF vs. controls in the hippocampus, in studies with animal models (mice) which overexpressed the human amyloid precursor protein (hAPP) [29]. Also, Cerebrolysin had a favorable impact on neuroinflammation, neurotrophic factors, oxidative stress, excitotoxicity, neurotransmission, brain metabolism, neuroplasticity, neuronal apoptosis and degeneration, neurogenesis, and cognition in animal models [28]. The presumed mechanism of Cerebrolysin in AD involves the activation of phosphatidylinositol 3-kinase, AKT, and glycogen synthase kinase-3β intracellular signaling pathway [28]. Cerebrolysin reduced amyloid plaque formation by regulating APP, and inhibits calpain, caspase, Bcl-2, and upregulates Bax, protecting neurons from apoptosis [20,30,31].

The clinical efficacy of Cerebrolysin was demonstrated over global functioning and cognition in several clinical trials, and improvements in behavior at high doses, or minor effects on daily living activities were also reported in these patients [28]. The most consistent benefit was observed in mild-to-moderate AD patients, but also several subgroups of moderate to moderate-severe patients [28]. Clinical benefits of Cerebrolysin were preserved for several months after the last dose administration, therefore the recommendation of a discontinuous administration regimen is supported by evidence [28].

Cerebrolysin reversed the reserpine-induced reduction in latency to immobility and prolongation of immobility time in the forced swimming test, decreased tumor necrosis factor-alpha (TNF-α) levels, elevated glutathione(GSH) levels, and BDNF cortical and hippocampal brain concentration, in animal models of depression [23]. Cerebrolysin elevated protein kinase A and nuclear factor kappa-B (NF-κB) cortical and hippocampal protein expression [23]. Other effects of Cerebrolysin detected on animals (rats) were: amelioration of mRNA expression alterations of protein-kinase B (AKT), CREB, and BDNF in the cortical and hippocampal tissues; elevation of norepinephrine, serotonin, and dopamine levels in cortical and hippocampal tissues; antidepressant effects, as well as attenuation of oxidative stress and inflammation [23].

A study that evaluated in-vitro human cerebral endothelial cell permeability during Cerebrolysin administration showed that tissue plasminogen activator (tPA)- and fibrin-impairments of endothelial permeability were significantly diminished and even reversed by this agent [24]. Cerebrolysin reduced tPA- and fibrin-augmented proinflammatory and pro-coagulation proteins, also [24]. Unlike the cerebroprotein hydrolysate, with a distinct peptide composition, Cerebrolysin had favorable effects on tPA- and fibrin-impaired permeability and elevated tight junction proteins, previously affected by experimental conditions [24].

In a dose-finding clinical trial, Cerebrolysin was administered in patients with moderate-to-moderately-severe (N=133, Mini Mental State Examination - MMSE=14-20) or mild (N=118, MMSE=21-25) AD [17]. Participants received Cerebrolysin, administered as 10, 30, or 60 ml diluted in saline solution, or placebo over 12 weeks (5 days per week for 4 weeks, and 2 days per week for another 8 weeks) and were monitored for 24 weeks [17]. At week 24, Cerebrolysin improved significantly the global clinical functioning with all 3 dosages and induced significant improvements in cognition, initiation of daily living activities, and neuropsychiatric symptoms [17]. However, treatment effects on total activities of daily living (ADL), and other secondary parameters (MMSE, Trail-making test) were not significant [17]. The overall treatment tolerability was good, and no safety issues have been reported [17].

A double-blind, randomized, placebo-controlled, multi-center, 4-week clinical trial enrolled 53 patients aged at least 50 years, admitted to a hospital with mild-to-moderate AD and no severe organic comorbidities [18]. The treatment group received Cerebrolysin 30 ml in 100 ml physiologic saline i.v. once daily 5 times/week, for 4 weeks [18]. After 4 weeks of treatment, Cerebrolysin-treated patients presented significant improvements in the ADAS-Cog, CGI-S, and MMSE scores vs. placebo-treated patients [18]. The rates of improvement were 82%, 62%, and 44% on ADAS-Cog, CGI-S, and MMSE in patients treated with Cerebrolysin, compared to 31.6%, 22%, and 17% in placebo-treated patients [18]. No significant improvement in the Cerebrolysin group was detected compared to the placebo group on the Geriatric Depression Scale (GDS), ADL (Activities of Daily Living), and IADL (Instrumental Activities of Daily Living) [18]. Only one case of febrile sensation was reported, but it was mild in severity and transient [18].

Another randomized, double-blind, placebo-controlled multicenter trial enrolled 242 patients diagnosed with VaD, and the primary outcome was the combined cognition and overall clinical functioning score (ADAS-Cog+ plus CIBIC+-Clinician's Interview-Based Impression of Change plus Caregiver Input) assessed after 24 weeks of treatment [19]. At the end of the study, ADAS-Cog+ improved with 10.6 points in the Cerebrolysin group vs. 4.4 points in the placebo group (significant difference, $p<0.0001$) [19]. CIBIC+ showed a mean improvement of 2.84 in the active treatment arm and 3.68 in the placebo arm, a statistically significant difference ($p<0.0001$ vs. placebo) [19]. Higher rates of responsiveness were detected in the Cerebrolysin group, as reflected by the combined ADAS-Cog+ and CIBIC+ (67.5% vs. 27.0%), and the odds ratio for achieving a favorable response using this combined score was 5.63 ($p<0.05$) [19].

According to a Cochrane systematic review dedicated to Cerebrolysin treatment in people with VaD (n=6 randomized controlled trials, N=597 participants), mainly mild to moderate forms (n=4 trials), cognitive function had a more favorable evolution during Cerebrolysin treatment (MMSE, ADAS-Cog+), although these observations were based on very low-quality evidence [20]. When response rates based on global function (CIBIC+, CGI) assessments were included, there was a beneficial effect of Cerebrolysin (n=2 studies, N=379 participants) [20]. Four trials reported adverse events, and data from two studies (N=379 participants) included in a meta-analytic format did not report any difference between rates of adverse events (very low quality of evidence) [20].

A prospective, open-label trial, a 2-year course of Cerebrolysin therapy, administered as repeated sessions every 6 months, in patients with a mild cognitive impairment-amnestic type (N=73 participants), had as its main objective to explore if this type of intervention may slow down or prevent the transition to clinically relevant dementia [21]. The results at 2 years suggest the existence of a slower cognitive deterioration in patients who received Cerebrolysin, compared to those who did not [21].

A comparison of the safety and efficacy of Cerebrolysin (10 ml), donepezil (10 mg), and a combination of both treatments (N=64, 66, and 67, respectively) in mild-to-moderate probable AD, in a randomized, double-blind trial, concluded there were no significant differences in cognitive, functional, and behavioral domains between interventions [11]. Improvements in the global outcome, however, favored Cerebrolysin and the combined therapy at week 28 [11]. Cognitive performance was also superior at the end-point in the combined treatment group more than in the other two groups, but the difference was not statistically significant [11]. The overall tolerability of the combined treatment was good [11].

Administration of Cerebrolysin i.v. infusions (10 or 30 ml) or placebo (normal saline) 5 days/week for 4 weeks in patients with mild-to-moderate probable VaD (N=41 participants) led to significant improvements of cognitive performance at 10 ml dose and diminished the EEG slowing with both dose regimes [32]. Also, a significant correlation between fast EEG power ratio and ADAS-Cog scores change from baseline to endpoint was observed in Cerebrolysin-treated patients [32]. The extension of this 4-week trial, which enrolled 33 out of the 41 initial participants, showed that at week 16, Cerebrolysin improved significantly cognitive performance at 10 and 30 ml, and also reduced qEEG significantly at 30 ml dose [33]. These results suggest the persistence of beneficial effects of Cerebrolysin on cognition and qEEG activity in VaD patients for at least 12 weeks after treatment administration [33].

In conclusion, most of the reviewed data on clinical trials supported the efficacy of Cerebrolysin (n=6 trials, N=699 patients) in AD and VaD, but their efficacy was not consistent across all the evaluated cognitive or functioning domains [11,17-19,32,33]. However, the cognitive function was consistently favorably influenced by Cerebrolysin, and a systematic review confirmed this effect [11,17-20,32,33]. Although the rate of conversion from mild cognitive impairment to AD under Cerebrolysin decreased in one trial, there is an obvious need to replicate these data, and the open-label design of this trial raises supplementary questions about the generalizability of its results [21].

Regarding the secondary objective of the review, preclinical studies indicate multiple hypotheses about the mechanisms of action for HPATE, mostly based on mitigation of the ischemic process and oxidative stress, a decrease of inflammation and apoptosis-like processes in case of stroke (Actovegin); also, HPATE may increase BDNF cortical and hippocampal brain concentration, while decreasing the oxidative stress and inflammation (Cerebrolysin) [22-24].

Table 1: Case series – demographics, baseline values of structured instruments administration, and treatment schedule

Patient no.	Age	Gender	Severity (baseline)	Treatment
1	68	Male	ADAS-Cog: 51 MMSE: 16 CDT: 4 NPI total score: 14 NPI distress score: 12 CGI-S: 3 GAF: 35	Donepezil 10 mg/day 12 months + Cerebrolysin 20 ml/day 10 days/month, 3 months, repeated after 3 months free of HPATE
2	72	Male	ADAS-Cog: 40 MMSE: 19 CDT: 5 NPI total score: 22 NPI distress score: 16 CGI-S: 4 GAF: 40	Galantamine 16 mg/day 12 months+ Actovegin 10 ml/day 10 days, followed by 400 mg q.d. orally 6 weeks, repeated after 3 months free of HPATE
3	80	Female	ADAS-Cog: 58 MMSE: 14 CDT: 1 NPI total score: 20 NPI distress score: 14 CGI-S: 3 GAF: 30	Rivastigmine 13.3 mg/day 12 months + Cerebrolysin 20 ml/day 10 days/month, 3 months, repeated after 3 months free of HPATE

ADAS-Cog = Alzheimer's Disease Assessment Scale - cognitive subscale, MMSE = Mini Mental State Examination, NPI= Neuropsychiatric Inventory, CGI-S = Clinical Global Impression - Severity, GAF = Global Assessment of Functioning, CDT = Clock drawing Test

CASE SERIES

This case series is based on repeated evaluations of 3 patients (two male, one female, mean age 73.3 years), all of them being diagnosed with Major Neurocognitive Disorder due to AD (probable), according to the DSM-5 criteria [34]. These patients presented memory, learning, and executive dysfunctions, accompanied by the gradual decline of these cognitive functions for at least one year before their baseline psychiatric evaluation, and no evidence of mixed etiology.

All patients were evaluated using brain MRI/CT scans, blood analyses, neurological exams, and psychological evaluations, to quantify the level of brain atrophy, and to exclude other possible diagnoses, e.g. VaD, dementia due to normal pressure hydrocephalus, etc. In all these patients frontal atrophy (mild to moderate), inferolateral regions of the atrophy of the temporal lobe (moderate), and medial parietal lobes atrophy were detected. These structural changes are consistent with data in the literature regarding AD neuro-imagistic parameters evolution [35,36].

The absence of evidence for folate or vitamin B12 deficiency, thyroid disorders, Parkinson's disease, Huntington's disease, HIV/prionic disease, head trauma, demyelinating disorders, and brain tumors was confirmed by the results of laboratory analyses and clinical examination.

Personal history or current diagnoses of abusive use or dependence on alcohol/sedative, hypnotic, or anxiolytic drugs/inhalants were investigated, and no significant data were found [37,38]. Patients were screened negative for drugs with potential negative effects on cognitive functioning (first-generation antipsychotics, antihistamine drugs, antidepressants with anticholinergic properties, etc.) [39].

The change in cognitive functioning during one year was the primary outcome of these case series, and it was based on two widely-used and validated instruments – ADAS-Cog and MMSE. Secondary outcomes were the Clock-drawing-test (CDT), the Neuropsychiatric Inventory (NPI), CGI-S, and the Global Assessment of Functioning (GAF) score changes from baseline to month 12, during the same period.

The interpretation of the CDT (which measures executive function, visual-spatial abilities, abstractization capacity, and attention) was based on a 0 to 10 scale, with higher scores reflecting the higher severity of dementia symptoms (Figures 1-3) [40].

At baseline, ADAS-Cog total score reflected low functioning on multiple domains in all three cases. The mean baseline MMSE score was 16.3, the ADAS-Cog score was 49.6, and the CDT score was 3.3. The Neuropsychiatric Inventory (NPI) reflected at baseline high scores on anxiety, irritability, and depression, with a mean overall score of 18.6, and a distress score of 14. The clinical global impression corresponded at baseline to a mean score of 3.33, and the GAF score was 35. All these instruments were administered at every 3 to 4 months (flexible visit regimen), for one year.

Figure 1: Clock test for patient no. 1

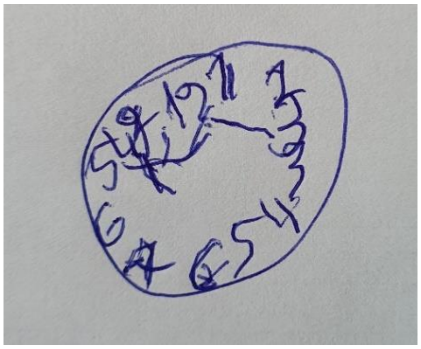

Figure 2: Clock test for patient no. 2

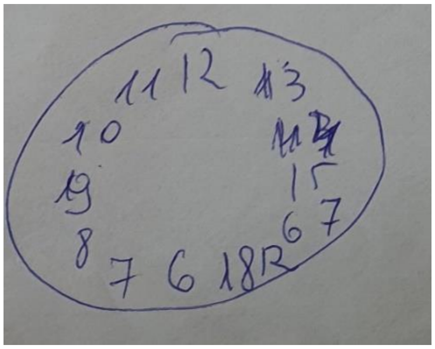

Figure 3: Clock test for patient no. 3

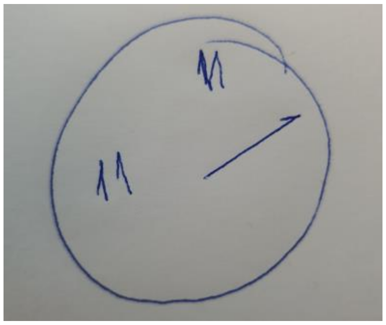
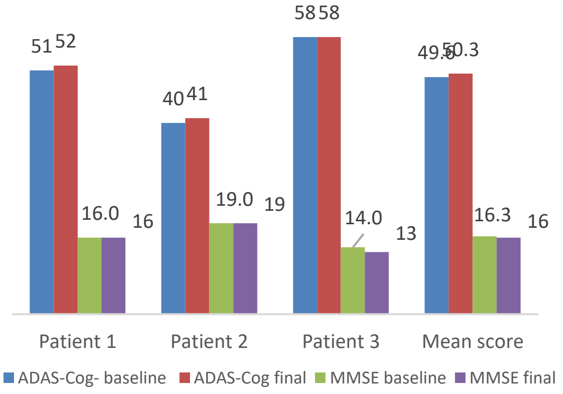


The therapeutic intervention consisted of HPATE, which was added to rivastigmine patches (n=1), oral galantamine (n=1), or oral donepezil (n=1). Actovegin was administered in one case and Cerebrolysin in two cases. The treatment schedule is represented in Table 1.

MMSE scores showed only a very small decrease during the 12 months of active monitoring (-0.33 points compared to baseline), and ADAS-Cog scores increased by 0.66 points (higher scores reflect more severe deterioration) (Figure 4). NPI total scores decreased with a mean of 7.6 points compared to baseline, and the overall distress with 4 points. The mean CDT score did not change after 12 months.

CGI-S and GAF scores also showed relative stability (no change for CGI-S, and -5 points on GAF).

Figure 4: Evolution of ADAS-Cog and MMSE scores from baseline to week 52



Both explored HPATE, Cerebrolysin and Actovegin, were well tolerated and they may be administered together with AChEIs because of their presumed synergistic effects.

This combination may be useful in stabilizing the overall cognitive status in moderate AD and in reducing the associated non-cognitive symptoms.

CONCLUSION

HPATE has been associated with potential benefits in patients diagnosed with AD and VaD as add-ons to AChEIs, or mild cognitive impairment as monotherapy. HPATE has a good safety and tolerability profile in AD or VaD patients. These conclusions are based on moderate and low-quality studies [11-15,17-20,32,33], therefore it may be considered that more clinical trials, with a randomized, double-blind design and a larger number of subjects are needed, to support HPATE positive effects on cognition. Regarding the impact of delaying the cognitive deterioration from mild cognitive impairment to clinically relevant AD using Cerebrolysin as monotherapy, data are even more inconclusive (one open-label study was found in the literature) [21].

AChEIs are associated with modest, but persistent cognitive benefits and these drugs may also reduce the mortality risk, a phenomenon which could be related to their cognitive favorable effects [41-43]. To augment the AChEIs effect, the administration of HPATE as an add-on may be useful for preserving the cognitive status or slowing the cognitive decline in patients with dementia. Therefore, HPATE may represent a useful and well-tolerated therapeutic option, and it may also favorably influence the evolution of non-cognitive symptoms in AD.

REVIEW

Individualized surgical antibiotic prophylaxis – why, when, and how?

Dan Corneci[1,2], Ligia I. Torsin[2], Cristina R. Filimon[2], Narcis V. Tănase[1,2], Emanuel Moisă[1,3], Silvius I. Negoita[1,3]

Abstract: *Surgical site infections (SSI) greatly concern clinicians, as they are associated with significant morbidity and mortality, prolonged hospitalization, and costs. Antibiotic prophylaxis plays a pivotal role among the procedures that are usually employed for the prevention of surgical-related infections. This narrative review aims to cover some of the particular situations when the clinician might consider individualizing antibiotic prophylaxis for a patient. With the rising incidence of multi-drug resistant bacteria carriage among not only hospitalized or institutionalized patients but also patients from the community, there might be a tendency to use extended-spectrum antibiotics for longer periods for surgical infection prevention. However, the inappropriate use of antibiotics increases the selection pressure, thus favoring the spreading of resistant bacteria. Moreover, specific patient characteristics or pathologies might need to be considered to customize the type, dose, or length of administration of an antibiotic as surgical prophylaxis. Using prosthetic material or prolonged surgeries with large fluid shifts are other situations when individualized antibiotic prophylaxis might be thought of. Keeping in mind that it is of utmost importance that everyone adheres to the current guidelines for surgical antibiotic prophylaxis, customization of local protocols according to well-thought-out strategies might prove beneficial in SSI prevention.*

Keywords: *surgical site infection; antibiotic prophylaxis; multi-drug resistance; personalized medicine*

INTRODUCTION

Current surgical antibiotic prophylaxis (SAP) is based on guidelines' recommendations that rely on solid evidence-based studies and, where data are lacking, on expert opinion. However, in practice, clinicians might encounter some particular situations that need to be addressed by tailoring antibiotic prophylaxis or choosing alternative strategies to prevent surgical site infections (SSI). At the same time, doctors must remember that a permissive large-spectrum antibiotic use or an unnecessary prolongation of antibiotic prophylaxis can lead to increased antibiotic resistance. Thus, a prudent decision must be made when choosing the right type and dose of antibiotic and the proper duration of SAP.

This literature review highlights the exceptions that may need a personalized approach regarding SAP, particularly the choice of antibiotics for patients colonized with multi-drug resistant bacteria (MDR), the length of antibiotic prophylaxis for specific surgeries, and the choice and dosing of antibiotics for special populations. In addition, other therapeutic options for lowering SSI are addressed.

SURGICAL ANTIBIOTIC PROPHYLAXIS GUIDELINES AND GUIDELINE COMPLIANCE

In France, Germany, and the USA, studies report overall compliance to guideline recommendations of about two-thirds when it comes to antibiotic choice for SAP and timing of administration [1–3], but the adherence rate is much lower in developing countries, varying widely between 18% and 50% [4–8]. Surprisingly, even in Italy, only 18% of cases in a small cohort study received appropriate SAP [9]. Table 1 summarises the doses and redosing intervals for the main antibiotics used in practice, according to guideline recommendations.

[3] Clinic of Anaesthesia and Intensive Care Medicine, Elias Emergency University Hospital, 011461 Bucharest, Romania

The most commonly reported deviation from the guideline was an unnecessary prolongation of SAP. For example, SAP was prolonged in France for more than 24 hours in 45.2% of surgical interventions [1], but their national guidelines allow 48 hours of antibiotic prophylaxis for certain types of surgery [10]. In Germany, unnecessary prolongation of SAP occurred in 30% of cases [3]. Lack of intra-operative redosing when needed is another deviation frequently encountered, being reported in around 20% of cases in developed countries [1,2].

Table 1: Dosage and redosing intervals for the main antibiotics used in surgical prophylaxis

Antibiotic	Pre-incision dose	First redosing interval	Subsequent redosing intervals
Ampicillin	2 g	+ 2h	every 6h
Ampicillin-Sulbactam	3 g	+ 2h	every 6h
Cefazolin	2 g (3g [1)])	+ 4h	every 8h
Cefuroxime	1.5 g	+ 4h	every 8h
Ceftriaxone	2 g	-	-
Ciprofloxacin	400 mg	+ 8h	-
Gentamicin	5 mg/kg [2)]	-	-
Metronidazole	500 mg	+ 8h	every 8h
Clindamycin	900 mg	+ 6h	every 8h
Piperacillin-Tazobactam	3.375 g	+ 2 h	every 6h
Vancomycin	15 mg/kg	-	-

[1)] Obese patients with weight>120 kg; [2)] adjusted body weight for obese patients

A qualitative study that interviewed surgeons and anesthetists in a tertiary hospital in Australia concluded that improvisation with novel SAP strategies is ubiquitous and confers a sense of reassurance for surgeons. However, these are not following guidelines or have no clinically demonstrated efficacy [11]. Lack of knowledge of guideline content, reliance on old habits and practices, lack of communication between surgeons and anesthetists, fear of medical malpractice linked to SSIs, environmental context and resources, or personal beliefs are some of the factors related to low adherence to guideline recommendations [12].

However, the good news is that concentrated efforts can improve guideline adherence [13–15]. Probably one solution would be to create local guidelines that follow international recommendations and adapt to particular contexts and local specificities.

MULTI-DRUG-RESISTANT BACTERIA ARE A CONCERNING PROBLEM

Globally, over 700,000 people die yearly from drug-resistant infections, and the predictions are that over 10 million people might die annually by 2050 if no preventive measures are taken [16]. Furthermore, a European prevalence study analyzing data from 2015 discovered that infections with MDR are on the rise, causing 6.44 deaths and 170 DALYs per 100000 population, with community-associated MDR infections representing a substantial proportion of the burden [17].

SSI makes no exception when talking about the burden of healthcare systems. SSIs have a pooled cumulative incidence of 5.6/100 surgical procedures in low and mid-dle-income countries (LMICs), strikingly higher when com-pared to the pooled cumulative incidence of 2.6 SSI/100 surgical procedures in the USA and 2.9 in Europe [18]. As the prevention of SSI supposes an antibiotic coverage of possible pathogens, it comes into question if patients with a high risk of being carriers of MDR might need an individualized approach to SAP.

A helpful model of adapting SAP comes from methicil-lin-resistant S. aureus (MRSA) SSIs. The incidence of SSIs caused by MRSA in the USA increased from 16% in 2003 to 21% in 2007, increasing mortality, hospital length of stay, and costs [19]. A meta-analysis confirmed that bundle measures for the prevention of MRSA SSIs in cardiac and orthopedic surgery, including nasal decontamination and glycopeptide antibiotic prophylaxis, decreased with 70% the risk of infection [20]. However, vancomycin is less effective than beta-lactam antibiotics for preventing SSIs caused by methicillin-susceptible S. aureus (MSSA) [20,21]. Thus, guidelines have rapidly adapted and recommend vancomycin use, in addition to routine prophylaxis, in patients who are colonized with MRSA or are at high risk of colonization [10,21,22].

Although data on colonization with antibiotic-resistant bacteria are scarce when talking about Gram-negative bacteria [23], more than 1 in 10 persons might be gut carriers of MDR in some countries [24]. Moreover, it is known that LMICs present a high incidence of infections with MDR [16]. Crowding, homelessness, low income, sanitation, and water sources are some factors associated with antimicrobial resistance in LMICs [25]. Comorbidities (diabetes, cancer, inflammatory diseases), extremes of age, recent hospitalization or antibiotic treatment, residency in a nursing home, and occupational risks, such as health workers or farmers, or veterinarians who frequently use antibiotics, or travel to LMICs are other factors associated with the acquisition of MDR infections [26]. An interesting study examined the dynamics of gut bacteria colonization of 20 European volunteer visitors to Laos. They registered a 70% colonization rate after 22 days of surveillance, but daily sampling revealed that all participants had acquired an extend-ed-spectrum beta-lactamase-producing Enterobacteriaceae (ESBL-E) at some point [27].

Infections following trans-rectal prostate biopsy (TRPB) are an actual problem for urologists. Guidelines generally recommend the utilization of fluoroquinolones as SAP for TRPB [10,21,22], but there is a rising concern that these antibiotics might be ineffective for the novel antimicrobial-resistance patterns [28]. The prevalence of resistant strains of E. coli for patients undergoing PB varies between 13 and 25% for stains resistant to fluoroquinolones, and 8% and 13% for strains resistant to cephalosporins and, more concerning, with ESBL carriage on the rise [29–33]. Furthermore, ESBL carriers have a higher risk of infections post-TRPB [34]. Thus, introducing rectal swabs that could detect potential carriers and tailored antibiotic prophylaxis before TRPB might be a cost-efficient measure that might lower infectious complication rates after TRPB. Data from a meta-analysis [35] and other studies support this strategy [36]. Moreover, studies identified some risk factors associated with re-sistant-stains colonization, such as the history of the use of fluoroquinolones, previous hospitalization [37], travel his-tory [29], obesity or diabetes mellitus [34,38]; patients could be selected based on questionnaire to be further investigated in a cost-efficient manner for colonization.

In a cohort of patients with cancer undergoing gastrointestinal and gynecologic surgery, 17.5% were colonized with ESBL-E at admission. The risk of developing an SSI was twice higher in ESBL carriers versus non-carriers (RR, 2.16; 95% CI, 1.2-3.89)[39]. Similarly, in a prospective study including 3700 patients undergoing colorectal surgery from 3 hospitals in Israel, Switzerland, and Serbia, ESBL-E carriage more than doubled the risk of SSI (OR, 2.36; 95% CI, 1.50–3.71). Interestingly, the prevalence of ESBL-E carriers differed significantly between countries: 9.4% in Serbia, 12.0% in Switzerland, and 28.8% in Israel [40].

Among 360 patients who underwent abdominal surgery in a university hospital in Thailand, 36% had preoperative enteric colonization with an ESBL-E, and 14.1% developed an SSI. Although colonization with ESBL-E represented an independent risk factor for SSI (aOR 2.4; 95% CI, 1.19–19.91), the study found no association between carbapenem surgical prophylaxis and reduction in SSIs. However, it must be kept in mind that the study was single-centered, included a small study group, the incidence of SSI reported was relatively high, the majority of SSIs were superficial, and the authors did not explain the choice of antibiotic prophylaxis [41].

The number needed to treat (NNT) is an important concept when analyzing the impact of SAP. A higher risk of SSIs would lead to a lower NNT regarding SAP, and thus a more significant impact on its incidence of SAP. Nutman et al. analyzed the effect of changing the standard cephalosporin-in-metronidazole prophylaxis for colorectal surgeries to individualized prophylaxis with ertapenem for ESBL-E carriers. SSI rates were 22.7% for non-carriers versus 15.8% for ESBL-E carriers (ARD, –7.7%, 95% CI, –14.6% to –0.8%), with a number needed to treat to prevent one SSI in ESBL-E carriers of 13 [42]. Starting from this study and considering the prevalence of MDR, Temkin et al. analyzed different clinical scenarios for SAP. Thus, if a broad-spectrum SAP were used only for MDR carriers, for a prevalence of 5% carriers, 260 patients would need to be screened to avoid one SSI. If the prevalence of 50% carriers, this number would drop to 26. However, if a broad-spectrum SAP were used for all patients, no matter if they are carriers, there would be 247 patients who would receive unnecessary broad-spectrum antibiotics for a real prevalence of 5% MDR carriers. In comparison, the number would drop to 13 patients if the real prevalence of MDR carriers is 50% [43].

Hence, there is a great need for MDR prevalence studies. These would offer the possibility to adapt local guidelines of SAP while lowering MDR-SSI and improving, at the same time, the costs and antibiotic stewardship programs.

Some centers from high-income countries have already adopted a personalized management pathway for patients undergoing elective interventions in visceral surgery [44]. The algorithm encompasses screening in patients at risk, very strict basic hygiene, targeted isolation who are MDR carriers or at risk of being carriers, and targeted surgical antibiotic prophylaxis [44]. This section may be divided into subheadings. It should provide a concise and precise description of the experimental results, their interpretation, as well as the experimental conclusions that can be drawn.

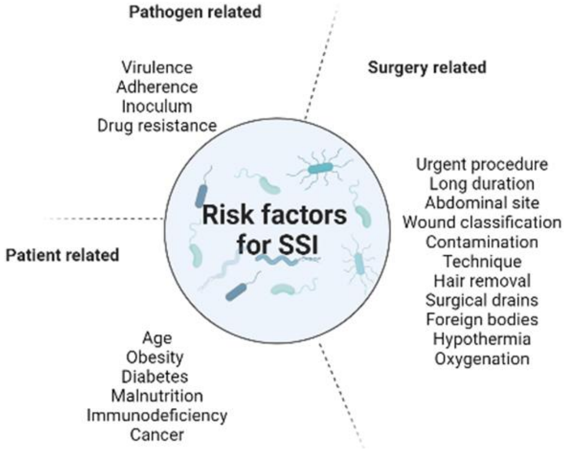
LESS IS MORE. ARE THERE EXCEPTIONS?

There is a bundle of risk factors associated with SSI (figure 1). The consensus recommendation for antibiotic prophylaxis is to administer a single dose for the majority of surgeries with clean or clean-contaminated surgical wounds. The exceptions that can receive a 24-hours postoperative antibiotic regimen include cardiac surgeries, head and neck surgery that involve the oral cavity, or some procedures that involve prosthetic materials (joint replacement, internal fixation of fractures, breast augmentation) [10,21,22]. The French guidelines are more permissive and accept a 48-hour postoperative antibiotic regimen for limb amputations, grade II open fractures, or craniocerebral surgical wounds [10].

During cardiopulmonary bypass (CPB), needed in most cardiac surgeries, an important increase in circulating volume due to pump priming can lead to a decreased concentration of the prophylactic antibiotic. A pharmacokinetic model study that included pediatric patients analyzed the serum levels of cefazolin before, during, and after cardiopulmonary bypass. Considering the higher ratio of priming volume needed for children during CPB, an additional bolus dose at the start of CPB improved the probability of target attainment by more than 90% [45]. When comparing bolus infusion versus continuous infusion of cefuroxime for the first 24 hours following CPB, plasma concentrations of cefuroxime were higher in patients receiving the continuous infusion [46]. An undergoing clinical trial that compares short-course and long-course SAP with either cefazolin monotherapy or combination therapy with cefazolin and vancomycin might shed some light on which strategy is best for CPB [47].

Regarding intraoperative antibiotic redosing, there is limited clinical evidence, but there are expert opinions that sustained a more aggressive redosing based on pharmacokinetic data. In a recent meta-analysis, Wolfhagen et al. ad-dress this question and the clinical utility of intraoperative re-dosing; the findings attest to the beneficial results of redosing, but the certainty of the evidence was low [48]. The question of redosing will persist in literature until some results of well-powered RCTs will arise.

Figure 1: Risk factors associated with surgical site infections



Orthopedic surgery is another field of interest when talking about SAP. A retrospective cohort study analyzed standard SAP versus a one-week course of antibiotic prophylaxis after total joint arthroplasties. Infection rates dropped from 2.1% to 0.4% for total knee arthroplasties and from 4.3% to 1.1% for total hip arthroplasties, respectively, for patients that received seven days of antibiotics [49].

Another similar study proposed the use of extended postoperative oral antibiotic prophylaxis for seven days for patients with a high risk of infection after total joint arthroplasties – are diabetic, active smokers, obese, or have other conditions associated with risk for infections. High-risk patients that received extended antibiotic prophylaxis had similar infection rates to low-risk patients, with a number of needed to treat 57 patients to prevent one prosthetic infection [50].

Although using an extended course of antibiotic prophylaxis may decrease infection rates, further studies need to weigh the risk of increasing antimicrobial resistance, the costs, and the risk of developing Clostridium difficile infections before recommending the routine use of extended antibiotic strategy use.

PATIENT PARTICULARITIES

1. Allergic patients

Allergy to β-lactam antibiotics is one of the most commonly cited adverse drug reactions, with a reported prevalence of around 10% in western countries [51,52]. But among inpatients with an alleged penicillin allergy, only 5% had a positive penicillin skin test [53]. Moreover, cross-reactivity rates of allergic reactions between penicillins and 1st generation cephalosporins are 1% and even smaller when using 3rd generation cephalosporins [54]. Still, when it comes to SAP choice, many clinicians opt for using alternative antibiotics, such as clindamycin, vancomycin, or gentamicin, when a patient claims to have an allergic reaction to penicillin [55].

There is a four-fold increased risk of SSI (95% CI 1.37-10.47) when clindamycin was used instead of the standard cephalosporin SAP for patients with declared allergy to penicillin that underwent free tissue transfer in head and neck surgery [56]. Furthermore, a meta-analysis that investigated SSIs after cardiac surgery discovered that β-lactam is superior to glycopeptides for the prevention of chest SSI (RR, 1.47; 95% CI 1.11–1.95). Blumenthal et al. also concluded that second-line antibiotic use raises the odds of SSI by 50% [55]. Besides SSI, alternative regimens used for patients labeled allergic to penicillin may lead to increased antibiotic resistance, hospital length of stay, and higher costs [57].

Clinicians should develop strategies to rule out spurious β-lactam allergies. A first step may include a thorough his-tory investigation or a standardized questionnaire that could rule out falsely labeled patients and select high-risk patients for further investigation. Further, selected patients may follow a classical allergy diagnosis (skin prick or patch test or a specific IgE test) or be subjected to an intradermic test done by properly instructed personnel [57,58]. Thus, labeling patients with reported penicillin allergies could lower SSIs and improve antibiotic stewardship.

2. Obese patients

Obese patients may present a challenge when it comes to adequate antibiotic dosing. Guidelines consider that serum and tissue concentrations of certain drugs vary in obese and non-obese populations. It is recommended that the dosing of vancomycin and aminoglycosides be based on total body weight and adjusted body weight, while the dose of cefazolin be increased from 2 g to 3 g for patients over 120 kg [21,22], or even to 4 grams for bariatric patients with a BMI over 35kg/m2 [10]. Although this is backed up by pharmacokinetic studies [59], some opinions do not support the increased dose of cefazolin in obese patients [60].

Microdialysis studies are contradictory. Palma et al. concluded that 2 g of cefazolin, reduced at 4 hours intervals, is enough and effective to prevent infections caused by bacteria with a MIC up to 2 mg/l, even in obese patients [61]. On the contrary, Brill et al. support higher dosages of cefazolin in obese patients, arguing that distribution to the subcutaneous adipose tissue is reduced and the probability of target attainment is decreased for MIC of 2mg/l or higher [62].

Another study that included 12 obese pregnant women undergoing cesarean section suggested redosing cefazolin after 2 hours, following either a 2 or 3 g initial bolus [63]. Finally, a swine model that targeted a plasma and tissue concentration of 4 mg/l proposes a weight-based cefuroxime dosage of 20 mg/kg [64].

Until future pharmacokinetic studies and controlled trials bring hard evidence regarding the right dose of antibiotic for obese patients in SAP, it may be more prudent to follow guideline recommendations, even though they are based on expert opinion.

3. Organ recipients

In solid organ transplantation, numerous factors contribute to increased rates of infections: prolonged pre-transplant hospitalization, exposure to antibiotic treatment, immuno-suppressive therapies, donor-derived infections, or the rising number of MDR portages [65].

One strategy for lowering SSIs associated with MDR is screening recipients and using an extended-spectrum anti-biotic as prophylaxis for MDR carriers.

For example, in one study, out of 61 patients screened for VRE colonization before liver transplant, 27 (44%) were carriers. All carriers received daptomycin in addition to GNB antibiotic as SAP, and only 3 developed postoperative VRE infections [66]. In another cohort of patients who under-went liver transplantation, 13.3% were ESBL-E carriers. Known carriers received a carbapenem as SAP. In ESBL-E carriers the risk factors associated with ESBL-E infection were colonization with K. pneumoniae, long-term spontaneous bacterial peritonitis prophylaxis with quinolones, antimicrobial treatment >3 days within the month before LT, and MELD ≥25. In the early postoperative period, ESBL-E infections were significantly lower in patients who received tailored SAP versus those who received standard SAP (29.8% vs 63.6%, p=0.04) [67]. Similarly, ESBL-E stool carriage before liver transplant in a pediatric population was associated with the emergence of ESBL-E-caused infections (OR = 4.5, 95% CI 1.4–17.4), although ESBL-

E carriers received imipenem as SAP, while non-carriers receives cefoxitin or piperacillin-tazobactam [68].

Another strategy is to broaden the spectrum of antibiotic prophylaxis for all solid-organ transplantation. A single dose of ertapenem prophylaxis instead of cefazolin reduced by a third of early infections caused by ESBL-E in kidney transplant recipients in a Spanish university hospital. Moreover, ESBL-E infection was associated with cefazolin prophylaxis and acute rejection, while ertapenem did not seem to increase the incidence of Clostridium difficile or other MDR infections [69].

Donor respiratory cultures do not influence post-transplant infections in non-lung recipients [70]. Still, prophylactic antibiotics must provide coverage for pathogens isolated from the donor lung or the recipient before lung transplantation [22,71].

Spanish Society of Transplantation recommends for patients colonized with ESBL-E a large-spectrum antibiotic prophylaxis regimen before solid-organ transplantation, avoiding, as possible, carbapenem use [71]. Infectious Disease Socie-ty of America also mentions that prophylactic antibiotics may need to be altered according to the recipient's pathogen isolation before liver transplant [22].

In conclusion, data support as a strategy for solid-organ receivers pre-transplant surveillance of MDR carriage and tailored SAP. Another strategy might be the use of broad-spectrum antibiotic prophylaxis for all solid-organ recipients, but this might favor the development of resistance.

4. Extremes of age

Particularities in the pharmacokinetics of antibiotics emerge not only in neonates but also in elderlies. Membrane permeability, plasma protein binding, and total body water, which vary significantly at the extremes of age compared to healthy adults, determine the final plasma concentration and tissue concentration of antibiotics. Moreover, the metabolism and elimination of antibiotics are also different from adults, as neonates have immature metabolic pathways, and the elderly might suffer from liver or renal failure. Furthermore, the elderly are at risk of adverse effects due to polypharmacy and potential drug interactions [72,73].

Although therapeutic drug monitoring might be the correct way of dosing the antibiotics in these two age groups, it is too sophisticated and expensive to be applied in the real world just for surgical antibiotic prophylaxis.

Thus, a correct antibiotic dose calculation for both groups based on guide-line recommendations is essential.

COMPLEMENTARY MEASURES FOR PREVENTION OF SSI

In addition to classical antibiotic prophylaxis, novel complementary measures rise to prevent surgical site infection, including local or topical measures and systemic decontamination.

For example, a local prolonged release of antibiotic containing a matrix of polymers and lipids doxycycline was tested for the prevention of sternal wound infections after cardiac surgery [73]. The prospective, single-blind randomized controlled multicentre study, counting 81 patients, proved that this novel compound, D-PLEX, was safe for cardiac surgery patients. There were zero sternal wound infections in D-PLEX treated patients, but larger scale studies are needed to prove its efficiency versus standard care [74].

Another study that tested dual-topic antibiotic application before sternotomy wound closure showed encouraging results [75]. The observational study analyzed over 2500 patients after cardiac surgery, revealing that dual antibiotic topical prophylaxis had the lowest rate (1.1%) of sternal wound infection versus the group treated with topical vancomycin (2.2%) and the control group (4.5%).

Furthermore, there was a higher rate of occurrence of gram-negative bacteria in the control group (3.4%) versus the vancomycin (1.2%) and the dual antibiotic group (0.6%) [75].

Although digestive tract decontamination was greatly debated, its application might prove beneficial in SSI prevention [76]. A retrospective study from the Netherlands evaluated the strategy of selective oral digestive tract decontamination with the use of an oral solution with amphotericin B 2%, colistin 2% and tobramycin 2% in patients with oesophageal carcinoma who underwent minimally invasive esophagectomy. The study's conclusions revealed a lower rate of fistulas and postoperative pneumonia (36.9% vs. 20.1%) in the group of patients with selective digestive decontamination versus the control group, but without an impact on mortality rates [77]. A similar regimen for digestive tract decontamination was used in a RCT that included patients with colorectal cancer scheduled for elective surgery with a primary anastomosis. Compared to the control group, the patients randomized to the oral decontamination group had similar anastomotic leakage rates but significantly lower rates of infectious complications [78].

Faecal microbiota transplantation arises as a novel method of SSI prevention. It is a proven way of gastrointestinal decolonization of multidrug-resistant bacteria, and it is beneficial for the treatment of refractory Clostridium difficile infection, with success rates close to 90% [79]. A review of the literature showed that more than half of the patients achieve digestive decontamination for multidrug-resistant bacteria when treated with faecal microbiota transplantation [80].

Bacteriophage use might be another novel therapy to help prevent SSIs. However, there is only limited evidence from small case studies and experimental trials. The bacteriophages are virus-like structures with bacterial cell lysis activity. A series of patients from Finland with multi-drug-resistant bacterial infection after cardiothoracic surgery received conventional targeted antibiotics and bacteriophages, successfully treating infections in 87% of patients. The literature cites applications of bacteriophages in the surgical setting with topical application of phage solutions to a surgical wound before closure [81-83].

CONCLUSION

All things considered, surgical antibiotic prophylaxis remains a vital tool in the fight against SSI. Following the general rules of good practice, antibiotic prophylaxis could be individualized when clinicians face MDR carriers, allergic, obese, immunosuppressed or elderly patients or when the surgical intervention calls for prosthetic material insertion, large fluid shifts or prolonged duration. There is, of course, a need to develop evidence-based local SAP policies in accordance with the local prevalence of MDR and the incidence of SSIs.

REVIEW

Medical and chemical evaluation of robotic surgery methods; A review study

Hoseinali Danesh[1], Javad Rahmati[2,3], Mahdieh Khodabandeh[4], Seyed M. Hemadi[5], Alireza Bahmani[1]

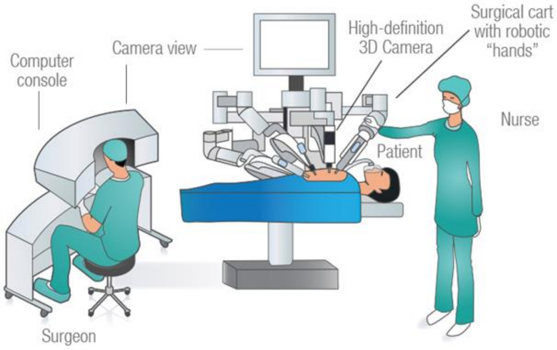
Abstract: *Along with the advances in medical science, surgical methods have also undergone many advances. Today, with the advancement of technology in all fields, including medicine, robots have entered medical science. These robots have many uses as well as advantages and disadvantages that they enjoy in Iran and other countries. In this study, it was addressed. This study is a review of robotic surgery methods in Iran and other countries in the form of a review study. This study is a conceptual review. The steps performed are 1- Designing a research question, 2- Searching and extracting research-related studies, 3- Selecting related studies, 4- Tabulating and summarizing information and data, and 5- Reporting results. The results showed that robotic surgery in operations such as brain, kidney, open heart, liver, eye, laparoscopy, dental surgery, coronary artery surgery, hysterectomy, lymphadenectomy, general surgery, obstetrics, head and neck, shelf Chest, urology, endoscopy, colonoscopy, ear, nose, and throat are used and have advantages such as three-dimensional vision, flexible rotation of the instrument, reduction of surgeon hand vibration with vibration filter, ease of surgery and the ability to create the required patterns It reduces the volume of blood lost during surgery, the length of stay in the hospital, the amount of pain, and subsequently the number of analgesic doses consumed in the postoperative ward. Disadvantages include the relative increase in operating time, the high cost of robots, and the physician's lack of sensory perception of the patient's environment.*

Keywords: *robotic surgery, surgery, robotics*

INTRODUCTION

From the past until now, surgery has been known as a treatment for some diseases, but it was performed due to its many limited complications. Along with the advances in medical science, surgical methods have also undergone many advances [1]. In traditional surgery, the surgeon has to make larger incisions to perform the surgery and damage a large amount of tissue in the patient's body. This increases the likelihood of surgical complications such as pain, bleeding, and infection, and prolongs the patient's recovery time [2-5]. Given the problems that exist in open surgery, surgeons have sought to minimize harm to the patient by creating new tools. This led to the emergence of a new approach called minimally invasive surgery (Figure 1) [6-7].

Figure 1: Robotic surgery



Today, with the advancement of technology in all fields, including medicine, robots have entered medical science. In medical science, surgery and operations in which robots are directly or indirectly involved are called "robotic surgery" [8].

Robotic surgery is performed by making several small incisions in which the surgeon can be present without the patient's bedside and remotely while having three-dimensional vision by controlling the robot arms that have a range of motion similar to human hands and wrists and around Are placed on the operating table to perform surgery (Figure 2) [9]. Today, robots have become a very useful tool to help doctors, and their irreplaceable role in medical science is increasing every day. That's why the US National Institutes of Health has significantly increased research funding. The NIH budget for this project for 5 years is $ 2.3 million [10]. The difference between a robot and a human is not negligible in many ways. Robotic surgery, compared to traditional surgery, results in smaller incisions, increased accuracy, flexibility, better visual control, and reduced pain and wounds, which leads to less time spent in the hospital. And recovery time is faster [11].

Among the benefits of robotic surgery can be; Reduction of the long recovery period after surgery, reduction of postoperative pain, reduction of the possibility of postoperative infection, reduction of hospitalization time, no need to break the sternum and open the chest in open surgeries, rapid healing of wounds, in the availability of certified surgeons with unique capabilities in more locations, greater accuracy, elimination of surgeon hand vibration, continuous and 24-hour operation 24 hours a day without fatigue. In addition to having many benefits, according to robotic surgery studies (Figure 3).

Disadvantages are including: increasing the distance between doctor and patient, reducing the speed of communication with equipment and monitors, increasing the possibility of cutting the wrong place, the possibility of disconnecting the surgeon from the operating room, low network security, and the possibility of hacking communication, patients' reluctance to use this equipment and technology, Expensive robots, lack of assistance for the doctor, lack of sensory perception of the patient's environment by the doctor. Many operations by surgical robots such as brain surgery, kidney, open heart, liver, eye, laparoscopy, dental surgery, Coronary artery surgery, hysterectomy, lymphadenectomy, general surgery, obstetrics, head and neck, chest, urology, endoscopy, colonoscopy, ear, throat, and nose have been successfully performed [10]. The high accuracy of some surgical robots makes it possible to perform very difficult surgeries such as vitreoretinal surgery and eye vitrectomy in a favorable manner [12].

There are several types of surgical robots. One of them is Heartlander, which is known as the smallest surgical robot in the world. Zeus robot is another robot. The other robot is the Da Vinci robot, which is known as the best robotic surgery system in the world and is made by a single commanding company. The system was approved by the US food and drug administration in 2000. In the meantime, other countries have also started working.

In Iran, the Sina robot surgeon (Da Vinci's rival), was developed by researchers at the Tehran University of Science in collaboration with researchers at the Sharif University of Technology. Its unique feature compared to the Da Vinci robot is that it measures the force applied to the patient's body and transmits it to the surgeon through the surgical console, and its price is estimated to be one-third of the American version [10]. Although we are facing the development of surgical robots around the world, a review of scientific products in the field of surgical robots shows that the United States, China, and Japan are the three leading countries in this field, respectively, and Iran is in 15th place.

Figure 4: Robot-assisted kidney surgery results similar to those of traditional methods

The trend of scientific production in this field started in 1990 and has been moving forward with a gentle slope and has gone through an upward trend since 2001. This trend has continued upward with fluctuations in different years. The results indicate that. There are few scientific developments in this field and few countries, universities, authors, and publications have addressed this issue [13] (Figure 4). According to studies, efforts should be made to recognize The right requirements to make it possible to use robotic surgery worldwide [14]. Therefore, this study aims to investigate robotic surgery methods in Iran and other countries in the form of a review study.

METHOD

This study is a conceptual review. The steps performed are 1- designing a research question, 2- searching and extracting research-related studies, 3- selecting related studies, 4- tabulating and summarizing information and data, and 5- reporting its results.

SEARCH AND EXTRACTION OF RESEARCH-RELATED STUDIES

First, articles were researched by researchers. Researchers first extracted related keywords using the MeSH strategy. Search for resources using the keywords robotic surgery, surgery, robotics, robot surgeon in Persian databases Barekat, Iran Medex, Irandoc, Magiran, SID and using the English keywords telesurgery, Robotic surgery, in Google scholar databases, Scopus, science direct, PubMed, web of science were conducted from 2013 to 2021 in October and November 1400. These words were searched separately and also as a combination of two words together using Boolean operators. To increase the validity of the study findings and control the bias in data entry, the search process, selection of studies, and decision-making on entering or constructing the study and evaluation of the full text of the articles were performed by two independent browsers. This process was overseen by a third party.

Inclusion criteria include all articles that have examined robotic surgery and their full text is available and written in Persian and English. Exclusion criteria were studies unrelated to the title

EXTRACTING ARTICLES ACCORDING TO INCLUSION CRITERIA

Using the above keywords at the end of the search, including 37 articles from Persian databases and 105718 articles from international databases and a total of 105755 studies were collected. The studies were reviewed based on inclusion criteria. The selection of related studies was done in such a way that first a list of titles and abstracts of all articles in databases is prepared by researchers. And if after reading the title and abstract, it was not possible to decide on the study, the full text was studied. Then, the related articles entered the research process independently, and finally, 43 articles were included in the study.

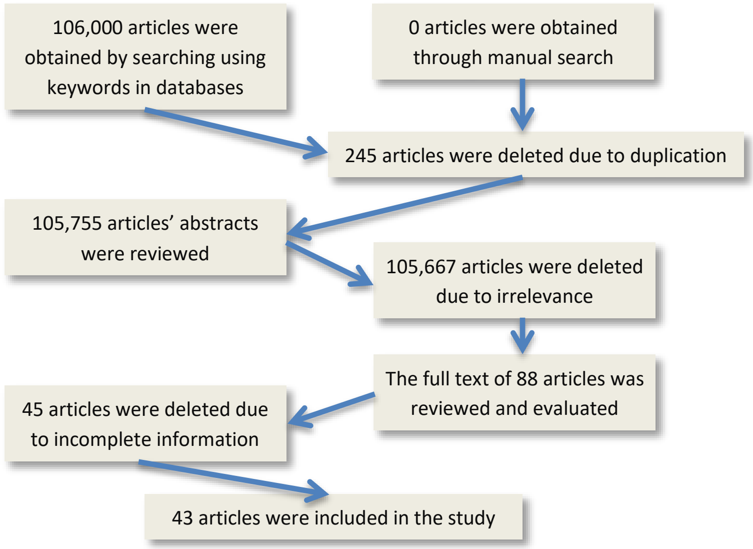
TABULATING AND SUMMARIZING INFORMATION AND DATA

At this stage, after the data has been extracted, all study data will be summarized based on the name of the first author, year, place, title, tools, or research elements in the relevant table.

REPORTING THE RESULTS

After reading the summary and full text of the articles related to the research topic, the desired information was extracted for writing. Information required for each study included author name, year, place, type of study, sampling method, data collection tool, and results. Finally, the information obtained from the articles was categorized and finally reported in the full text of a review article.

Figure 5: The schematic method



106,000 articles were obtained by searching using keywords in databases
0 articles were obtained through manual search
245 articles were deleted due to duplication
105,755 articles' abstracts were reviewed
105,667 articles were deleted due to irrelevance
The full text of 88 articles was reviewed and evaluated
45 articles were deleted due to incomplete information
43 articles were included in the study

There are many surgical robots or intelligent medical assistants in the field of medicine, but to conclude which of these robots is better, you must first assess the time and place conditions and services, because each of these robots is in a field of activity and it must be admitted that they also have limitations [15,16].

Robotic technology allows general surgeons to operate with great precision, and areas that are difficult or even impossible to reach by humans can be accessed using a robotic system. The robotic surgeon's arms can rotate up to 280 degrees. All this brings better results for the patient. Iranian specialists have succeeded in gaining the technical knowledge of this robot surgeon and the technical knowledge of the mechanism design process, hardware, and software Robots have also been achieved [17]. The results of studies conducted in Iran in the field of robotic surgery are as follows.

The results of measuring and recording the time required to start the robot, the ease of working with the robot, the quality of the robot in response to the surgeon's instructions, the accuracy of the robot movements, the ability of the robot to provide full image coverage, no shaking or shaking image, The indefatigability of the robot in prolonged surgeries, the absence of unwanted movements and the lack of errors in movements indicate the safety and efficiency of the robot and its satisfactory performance during surgeries. Although launching a robot requires time and initial work, the results show a reduction in total operation time in most cases. The smoothness of motion, stability and no-image shake are among the advantages of the robot holding the laparoscope over the human hand, so this robot can be a good alternative for the person holding the camera.

The next step will be to simplify work with the device by upgrading the software and conducting more clinical studies to evaluate robot performance comparisons [18]. Studies have shown that three-dimensional vision, flexible rotation of the instrument, reduction of surgeon hand vibration with the help of a vibration filter, ease of surgery, and the ability to create the required patterns are the characteristics of surgeon robots. Also, in general, the volume of blood lost during surgery, the length of hospital stay, and the amount of pain, followed by a reduction in the number of analgesic doses consumed in the postoperative ward and the time to return to a normal diet and normal activity compared to the laparoscopic procedure is reduced.

On the other hand, the results of the research have shown that the duration of the operation by the robot and the cost of surgery are longer than the laparoscopic method.

DISCUSSION

Robot surgery is not necessarily more expensive than laparoscopic surgery. Evidence now suggests that robotic surgery has a permanent role to play in the future of surgery. Therefore, surgeons should be actively diligent in the development of robotic surgery and begin preliminary and randomized studies with high prognosis and quality in this field [19]. The results showed that the use of robot traps in hip arthroplasty, in addition to providing more accurate 3D images for the surgeon to assess the depth and size of the acetabular cavity, reduces the risk of displacement or dislocation of the replaced joint. Reduces the risk of complications such as infection and site bleeding for the patient as well as readmission to the hospital. The results of studies show that robotic surgeries have effective applications as a minimally invasive method. Therefore, they can be gradually replaced by other surgical methods, but what is important is to pay attention to improving skills in the field of relevant new inventions, strengthening infrastructure, and allocating sufficient money to be able to use advanced technologies desirably and efficiently. Used for the benefit of the patient and the surgeon and other members of the treatment team [20]. It is true that the elimination of the natural vibration of the surgeon's hand, reducing the possibility of infection and postoperative infections, the possibility of a deeper vision of the operating field, and the creation of small and delicate incisions instead of large incisions by microscopic robots are the advantages of using robotic surgery. However, it is possible to reduce the feeling of tissue specificity under the operation by the surgeon, reduce the speed of communication with equipment and monitors and the possibility of a twenty-five-second delay on the monitors can also be considered as disadvantages of remote surgery. Remote surgery is performed by robots and advanced medical systems, but due to its cost and lack of strong technological and communication infrastructure, this method has not yet been properly transferred to developing countries and is limited to developed countries [21].

Limitation of tactile data Using graphic data It was thought that robotic surgery would be used more, but this did not happen. Reasons for this include lack of public awareness of the benefits of this method, patients 'refusal to have robotic surgery, and surgeons' desire for traditional surgery [22]. A study showed that the use of viewfinders will be effective in reducing the cost, weight, and dimensions of equipment and also simplifying some medical operations. It should be noted that the use of observers strongly depends on the type of operation used and not all of these methods are yet clinically applicable because there are many challenges in ensuring the performance and safety of these methods. However, the multidisciplinary nature of this subject provides a wide field for study and research [23]. Robotic surgery has made slow progress due to cost and patent protection. But now we are seeing an increase in the number of new robotic surgery systems. Several systems are CE-certified, while in the EU alone TransEnterix Senhence has received FDA approval, and several more are currently being tested, which will increase competition and reduce costs by approving these new robots. In the future, robotic surgery will be more common than manual surgery [24]. A "driver's license" is seriously required for robotic surgery. Ideally, a certified training program is required to define a robotic surgeon and ensure a high level of work. And the training pyramid must start from the ground up, so that, with the effectiveness of the training, robotic surgery is safe for the patient and the surgeon [25]. Robotic surgical systems were divided into open/closed, image-based/imageless, and active/inactive/ systems. The main goal is to improve the accuracy of operations. It should be noted that regardless of the typology of the robotic system, the surgeon is responsible for planning and approving the use of the type of operation. Accurate and consistent execution of instructions is entrusted to robots. Every surgeon, when considering which robotic system to use, must correctly evaluate their differences [26].

One of the most important issues in remote surgery is the touch feedback system. Although surgeon robots increase the surgeon's agility, have less vibration of the surgeon's hand, and have better vision, they reduce their ability to understand. Other disadvantages of robotic surgery include the possibility of a twenty-five-second delay on monitors. Depending on the doctor's condition, the delay between when the surgeon sees the knife moving and the incision is less than one-fifth of a second. It is performed and increases the probability of cutting in the wrong place and the risk of surgery and the cost of the required equipment [27]. The amount of bleeding after robotic surgery is low and severe bleeding, even if it is small, requires embolization or tracheotomy to control the bleeding. Large tumors, preoperative anticoagulant use, and a history of previous radiation are associated with an increased risk of bleeding after robotic surgery [28]. In comparison with immediate and long-term results, no difference was observed in the duration of the operation, the number of times the blood transfusion was required, and the occurrence of severe postoperative complications. Compared to traditional surgical methods, robotic surgery reduces the number and severity of postoperative complications and improves treatment outcomes [29]. In a study in the robotic surgery group, the rate of blood loss, length of hospital stay, and complications were lower, but the mean time of operation was longer compared to open surgery [30]. Operating times for robotic surgery are time-consuming due to the connection and stabilization of the instrument. The results of 260 cases of robotic surgery showed no increase in postoperative death [31]. Over time, with experience and innovation in platform design (Da Vinci), operating time is likely to decrease further [32,33]. However, a study showed that the benefits of robotic surgery have yet to be explored. Although the initial results are promising [34].

Also, studies conducted in other countries regarding robotic surgery are as follows. One study found no major complications during surgery. Kidney surgery with the help of robots by experienced robotic surgeons is a safe and repeatable surgery in selected cases and the result is excellent connective tissue function. The use of robotic technology can provide low complication rates, rapid recovery, and better connective tissue function [35]. Robotics in spine surgery is an emerging technology that promises plans. The accuracy of surgery in instruments implanted using robotics seems to be high. However, the effect of robotics on radiation levels is unclear and seems to depend on the technique and type of robot [36]. Robotic surgery greatly affects spinal surgery and is still safer and more efficient. Finally, it offers a better 3D image [37]. Robotic spine surgery was introduced in 2004. Robotic spine surgery has made great strides. This surgery is a reliable and accurate tool for spine surgery and has grown rapidly in recent decades and is still on the path of development and progress [38]. Artificial intelligence has tremendous potential to revolutionize the comprehensive care of the spine. It can assist surgeons in selecting preoperative patients, and surgical symptoms, and improving individual postoperative care. Robotic surgery, while still in its infancy, has a very clear vision for robotic spine surgery. Robotic surgery can reduce surgeon fatigue and improve surgeon technical accuracy [39]. Robotic systems are widely accepted in the United States and various surgical specialties. This innovative technology is still relevant in the field of spine surgery. These systems have potential benefits such as increased screw placement accuracy, reduced operating time, and reduced radiation. However, the various technical factors of these systems are constantly being re-evaluated to improve performance and achieve these goals [40]. Robotic surgery is also very effective in adult spinal deformity surgery [41].

Robotic hip arthroplasty was associated with a reduced length of hospital stay and reduced costs compared to conventional methods. However, robotic surgery was associated with readmission and the need for more blood transfusions [42].

Robotic surgery is an innovation in thyroid surgery that compensates for the disadvantages of conventional endoscopy. Robotic surgery has many advantages, including 3D imaging, motion scaling, and vibration elimination. Although robotic thyroid surgery is often associated with longer operating times than conventional open surgery, more robotic techniques are safer. Robotic surgery is compared to conventional open surgery or endoscopy. It is associated with several benefits such as quality of life, aesthetic results, reduction of neck pain and sensory changes, and reduction of discomfort in swallowing after surgery. According to surgeons, robotic surgery improves the patient's ergonomics. The time and cost of surgery in robotic surgery have been longer. Patient mortality was not different. The benefits of robotic thyroid surgery With conventional surgery, it is shown that robotic surgery can be an advanced surgical option for thyroid disease. Robotic thyroid surgery should be further developed as a surgical procedure for endocrinology, and head and neck surgeons have received this training, and robotic thyroid surgery is a surgical option [43].

Robotic surgery for the treatment of rectal cancer appears to be oncologically safe and appears to be better in terms of short-term complications and pathological quality indicators. The potential and proven benefits of robotic surgery should be considered. The benefits of robotic surgery for rectal cancer include improved three-dimensional vision, ease of use of the tool, improved surgeon ergonomics, and better access to narrow spaces such as the pelvis. However, studies have clearly shown the value of robotic surgery for patients and surgeons and need further studies [44].

Mesorectal robotics is a safe and sufficient technology for the treatment of rectal cancer and helps to maintain better urinary and sexual functions. Robotic surgery due to better wrist movements and better use of tools that facilitate autopsy, especially in narrow spaces, facilitates the operation by minimizing damage to the surrounding tissues as well as due to the magnified view [45].

Robotic surgery seems to be an effective method in terms of oncological and functional results and is effective in patient survival and its use is recommended in tumor staging and HPV status [46].

Robotic-assisted radical prostatectomy was less recurrent and had lower pain scores up to 6 weeks postoperatively compared to open radical prostatectomy. Compared to laparoscopic prostatectomy, robotic surgery improves urinary and sexual function. Robotic surgery had fewer complications for endometrial cancer than laparoscopy [47].

Mitral valve robotic surgery is well possible through a limited surgical procedure. Mortality around surgery seems very acceptable and possible. It is even lower than sternotomy. The rate of stroke was higher than sternotomy in the early stages of mitral valve robotic surgery but now appears to be at least the same. After robotic surgery, 1 in 4 people needed a blood transfusion. The rate of renal failure around surgery is low. One in 200 patients develops a wound infection. The length of hospital stay did not decrease. Due to the huge level of innovation in mitral valve robotic surgery, this method seems very satisfactory [48].

Robotic head and neck surgery are now regularly used in specialized centers for head and neck surgery. It is used in simple surgeries and easily accessible anatomical areas such as the mouth and throat. Disadvantages of this method include increasing the time required for the operation and increasing costs. For basal cranial, nasopharyngeal, or laryngeal surgery in patients with difficult anatomical conditions, systems with special surgical instruments for head and neck surgery should be developed. Despite the obstacles, we strongly believe that robotic systems will have a major impact on how we perform head and neck surgery over the next decade. Robotic head and neck surgery are recommended for better surgery in difficult areas, to reduce surgical complications, and to increase patient safety [49].

Robotic surgery in a rural head and neck center is a safe and appropriate treatment option and has very few side effects and this method is recommended [50].

A review of studies showed that robotic surgery has better overall survival than non-robotic resection of oral squamous cell carcinoma, and this method is recommended [51].

The number of female robotic surgeries has increased dramatically since the introduction of robotic surgery systems in Korea. Based on these data, it is expected that the continuous use of robotic surgery is widely used for both benign and malignant types of gynecological diseases. Many traditional surgeries are expected to be replaced by robotic surgeries [52].

A study on the application of robotic surgery in gynecological diseases showed that robotic surgery can significantly reduce blood loss, intraoperative complications, and length of hospital stay, but the rate of readmission and operation time Increasing. Robotic surgery has shown better results in the treatment of endometrial cancer [53].

The robotic system has overcome some of the shortcomings of laparoscopy, including three-dimensional vision limitation and hand tremors. Therefore, robotic surgery has taken many steps toward further progress in the field of general surgery. Although the safety and effectiveness of robotic surgery systems have been confirmed in most methods, in some methods robotic surgery has not been widely performed and is limited to a few highly specialized centers. Robotic surgery in hepatectomy, gastrectomy, esophageal surgery, colectomy, and pancreatectomy is performed unequally in the world, which may be related to the economic power of countries and the preference of surgeons, with the gradual reduction of the cost of robotic surgery systems and its standardization, we believe that robotic surgery will become gold and will become a standard method in general surgery, including surgical procedures as well as health insurance coverage [54].

The operating time for robotic surgery was 30% longer compared to laparoscopy. The rate of re-admission to robotic surgery is higher. Compared to laparoscopic patients, robotic surgery patients were hospitalized longer. There was no evidence of improved robotic surgery performance over surgery or clinical outcomes [55].

The rate of robotic segmentectomy has increased, and according to our study on robotic surgery, the operation time was longer, the blood loss rate was lower, and the hospital stay time was shorter. Our results show that robotic surgery can facilitate the function of complex anatomical parts [56].

Robotic surgery has become the preferred method for abdominal surgery. Robotic surgery is recommended when vaginal surgery is not possible. So far, gynecological robotic surgery has shown better safety and clinical results than laparoscopy. Robotics has been developed to overcome laparoscopic challenges and has led to technological benefits such as improved ergonomics, 3D visualization capabilities, skill and range of motion with the tool joint, and elimination of hand vibration. To date, robotic applications in benign obstetrics and gynecology include hysterectomy, myomectomy, endometriosis surgery, sacrocopopexy, adnexal surgery, tube re-anastomosis, and cerclage.

Robotic surgery may offer greater benefits than other methods in the obese patient population and more complex cases. Advances in robotic technology, such as telemedicine surgery, could revolutionize gynecological surgery. Finally, this robotic device is an additional minimally invasive surgical instrument that can help minimize laparotomy in women [57].

The use of robotic substrates in liver and bile duct surgery is growing rapidly. There is evidence that robotic surgery results are good. Robotic surgery is useful for managing complex cases such as iatrogenic bile duct injury, hepatic autopsy, or complex autopsy due to difficult anatomical positions.

We believe that, for selected patients, robotic surgery should be part of the treatment of complex liver surgeries [58].

According to studies, there is still room for the development of robotic surgery. Lack of close cooperation between scientists, institutions, and countries may have affected this issue. The process of industrialization of surgical robots in several developing countries, such as the United States, must be accompanied by the removal of technical barriers and increased international cooperation and exchange.

Removing barriers and developing global surgical relationships should seize the opportunity to improve the situation [59].

On the other hand, there is considerable variation in US hospital accreditation policies. However, the purpose of performing performance appraisals and monitoring is to improve patient outcomes. Extensive development and implementation of validation guidelines are recommended to optimize patient safety and outcomes [60]. The subject of training in robotic surgery is also very important.

The study showed that a lack of technical skills affects the results of robotic surgery. Therefore, physician education is very important [61}. The use of a standard curriculum for robotic surgery remains unclear. The choice of training methods and evaluation tools should be based on validity and application based on performance data. Clinical education seems to simulate effective education [62].

Also, in studies, the lack of clarity in the roles and responsibilities of nurses in robotic surgery and the lack of coordination for working conditions cause professional dissatisfaction and dismissal in nurses [63], which should also be considered.

CONCLUSION

Robotic surgery is one of the new and diverse technologies that the medical community at the national and international levels will have to use and enter this path. According to research, the results showed that robots can not be used in any way and relied only on manpower, because manpower, ie the same surgeons has mistakes, so these robots can not be left out.

Among the benefits of robotic surgery can be; Reduction of the long recovery period after surgery, reduction of postoperative pain, reduction of the possibility of postoperative infection, reduction of hospitalization time, no need to break the sternum and open the chest in open surgeries, rapid healing of wounds, in the availability of certified surgeons with unique capabilities in more locations, greater accuracy, elimination of surgeon hand vibration, continuous and 24-hour operation 24 hours a day without fatigue.

In addition to having many advantages, according to robotic surgery studies, it has disadvantages such as; Increasing the distance between doctor and patient, reducing the speed of communication with equipment and monitors, increasing the possibility of cutting the wrong place, the possibility of disconnecting the surgeon from the operating room, low network security and the possibility of hacking communication, patients' reluctance to use this equipment and technology,

The robots are expensive, the doctor does not have an assistant, and the doctor does not have a sensory understanding of the patient's environment. It must be adapted to other technologies and used to serve the people. Although we are facing the development of surgical robots around the world, a review of scientific products in the field of surgical robots shows that the United States, China, and Japan are the three leading countries in this field, respectively, and Iran is in 15th place.

The trend of scientific production in this field started in 1990 and has been moving forward with a gentle slope and has gone through an upward trend since 2001. This trend has continued upward with fluctuations in different years. The results indicate that there are few worldwide available scientific developments in this field and few countries, universities, authors, and publications have addressed this issue [13].

REVIEW

Risk factors for abdominal compartment syndrome in trauma – A review

Ruxandra A.M. Manole[1], Daniel Ion[1,2], Alexandra Bolocan[1,2], Dan N. Păduraru[1,2], Octavian Andronic[1,2]

Abstract: *Background and Aim: Abdominal compartment syndrome is a life-threatening complication that can occur in trauma patients and greatly increase their mortality. Although there is a better scientific understanding of the general phenomena involved in the pathogenesis of this complication, the particular risk factors and their implications in the trauma patient population are yet to be deciphered.*

*Methods: The authors conducted research through 3 electronic databases (PubMed, Scopus, and ScienceDirect) using the following search formula: "(ACS OR abdominal compartment syndrome) AND (*trauma*) AND (risk factor)". Subsequently, additional search formulas were used, including the risk factors taken into consideration (i.e. "shock", "hypotension", "acidosis", "base deficit", "coagulopathy", "retroperitoneal hematoma", "HOB elevation", "fluid resuscitation", "damage control laparotomy").*

Results: Throughout the 41 articles analyzed in this paper, 7 risk factors transcended and were further discussed: head of bed elevation/patient positioning, fluid resuscitation, the "lethal triad" of acidosis hypothermia and coagulopathy, Damage Control Laparotomy, shock/hypotension, retroperitoneal hematoma and demographics (age, gender, and race).

Conclusions: To summarize, many potential risk factors were evaluated for the envisagement of the present paper, but the ones that prevailed the most were excessive fluid resuscitation, shock/hypotension, retroperitoneal hematomas, and the lethal triad. Consistent with other studies, no connection was found between age, gender, or race and the development of ACS. Further studies should focus more on the likely involvement of damage control laparotomy and patient positioning, as well as hypocalcemia, in the unfolding of ACS in trauma patients.

Keywords: *abdominal compartment syndrome, trauma, risk factors*

INTRODUCTION

Trauma is considered to be the primary cause of death for people aged 1-44 years old in the United States [1,2], with similar demographics in the European Union [2]. There are two types of trauma, regarding the mechanism of injury: blunt and penetrating. Blunt trauma defines any injury caused by an impact with a dull surface or object and is most frequently encountered in motor-vehicle accidents, falls and assaults, whereas penetrating trauma represents an injury caused by a foreign object piercing the skin and creating an open wound, generally involved being firearms and stabbing [1]. Overall, blunt trauma accounts for 70% of all trauma cases [2].

Abdominal compartment syndrome (ACS) is a life-threatening complication that can occur in trauma patients and greatly increase their mortality. In 2006, the World Society of Abdominal Compartment Syndrome (WSACS) proposed a series of universal terms to use when referring to this intricate disease [3], which were later revised in a 2013 conference [4]. Throughout their research, major advances have been made toward a superior comprehension of the diagnostic criteria for ACS [5]. The prevalence of ACS in major trauma has been previously reported higher than 30% and the mortality rate greater than 60% [6].

Although there is a better scientific understanding of the general phenomena involved in the pathogenesis of ACS, the particular risk factors and their implications in specific

patient populations are yet to be deciphered. This article aims to address the particular occurrence of ACS in trauma patients, while also reiterating the information currently available in the literature to a greater extent.

The abdomen can be considered a relatively incompressible enclosed space and the intra-abdominal pressure (IAP) represents the steady-state pressure concealed within this cavity. IAP normally ranges between subatmospheric and 0 mmHg and changes slightly with respiratory movements. Pathologically, IAP rises with the accumulation of fluid in the abdominal cavity, space-occupying lesions, changes in the volume of its viscera, or conditions that limit the expansion capacity of the abdominal wall [3]. IAP is particularly elevated in critically ill adults, with a typical range of 5 to 7 mmHg [3].

Intra-abdominal hypertension (IAH) refers to a prolonged or repeated pathological elevation of IAP ≥ 12 mmHg [3,4]. Both IAH and ACS have been determined to be important independent predictors of mortality [7,8]. According to WSACS [3], IAH can be classified into 4 grades, as follows:

- Grade I: IAP 12-15 mmHg.
- Grade II: IAP 16-20 mmHg.
- Grade III: IAP 21-25 mmHg.
- Grade IV: IAP > 25 mmHg.

Malbrain et al. [9] suggested 4 subdivisions of IAH that were based on the time-length of symptoms:

- Hyperacute IAH defines a short-term increase in IAP over a couple of seconds-minutes, without pathological significance, due to sneezing, coughing, straining, or physical activity.
- Acute IAH is most commonly seen in surgical patients suffering from trauma or intra-abdominal hemorrhage. IAP rises abruptly over hours and imposes a high risk of producing new-onset organ failure, thus becoming a new clinical entity: ACS.
- Subacute IAH is a consequence of the interaction between casual and predisposing factors and develops over days.
- Chronic IAH progresses for months (i.e. pregnancy) or years (i.e. tumors, morbid obesity, cirrhosis with ascites), allowing the abdominal wall to accommodate the excess pressure through distension without decompensation.

A consensual research-based definition of the ACS was implemented by WSACS in 2013: ACS represents a sustained IAP > 20 mmHg, with or without an APP ≤ 60 mmHg, correlated mandatory with a new organ impairment/failure [4]. Abdominal perfusion pressure (APP) is the difference between mean arterial pressure (MAP) and IAP [3] and its relevance will be discussed within the pathophysiology of ACS.

Moreover, ACS can be classified into 3 types, depending on the duration and mechanism [3]:

- Primary ACS – involves acute or subacute IAH due to an intra-abdominal cause, most commonly trauma or surgery.
- Secondary ACS – subacute or chronic IAH originated from an extra-abdominal cause, most commonly burns or sepsis.
- Recurrent ACS – formerly labeled as Tertiary ACS, implies that a patient treated for primary or secondary ACS redevelops symptoms, most commonly acute IAH (“second-hit” phenomenon).

Given the fact that direct measurements are too invasive to be widely applicable in all patients [10], there have been numerous discussions regarding the indirect technique which most accurately estimates IAP. In 2006, the WSACS reached a consensus: IAP should be expressed in mmHg, measured via the bladder with a maximal instillation volume of 25 ml sterile saline solution, with the patient in a supine position at end-expiration, without abdominal muscle contraction and with the transducer zeroed at the mid-axillary line [3]. The standardized protocol reinforces that intermittent measurements should be conducted every 4-6 hours in critically ill patients with at least one risk factor for ACS [11].

METHODS

The authors conducted research through 3 electronic databases (PubMed, Scopus, and ScienceDirect) using the following search formula: “(ACS OR abdominal compartment syndrome) AND (*trauma*) AND (risk factor)”.

Subsequently, additional search formulas were used, including the risk factors taken into consideration (i.e. “shock”, “hypotension”, “acidosis”, “base deficit”, ”coagulopathy”, “retroperitoneal hematoma”, “HOB elevation”, “fluid resuscitation”, “damage control laparotomy”) and the terms “ACS” and “trauma”.

Three inclusion criteria were applied: the articles must be available in full text, written in English, and published no more than 10 years ago. The references of the selected papers were also checked for other relevant material. The resulting references were included in the current review, focusing on the pathophysiology of the abdominal compartment syndrome and its risk factors, particularly in the adult trauma patient population. In the end, a total number of 41 articles were included in this research.

RESULTS AND DISCUSSIONS

For a better understanding of the implications of various risk factors in the pathogenesis of ACS, a brief description of the key pathophysiological concepts is needed.

The abdominal cavity is a well-defined space limited cranially by the diaphragm, caudally by the pelvic floor, anteriorly and posteriorly by the abdominal wall, and contains numerous parenchymatous viscera such as the liver, spleen, pancreas or kidneys, as well as hollow organs such as the stomach, small intestine, colon, cholecyst or urinary bladder. Given the fact that this cavity represents a closed compartment, one can easily understand that the ACS behaves similarly to any other compartment syndrome in general – an increase in intra-compartmental pressure generates a compression over the blood vessels, initially resulting in a restricted venous and lymphatic flow, followed by an arterial blood supply impairment and subsequently entering a vicious cycle which generates and maintains cellular hypoxia [11,12,13].

The cause of elevated intra-abdominal pressure can differ between trauma, burns, or sepsis, but they all result in a molecular cascade that ultimately determines capillary leak syndrome, fluid extravasation, and interstitial edema [14]. Capillary leak refers to undesirable extravasation of fluid and electrolytes +/- protein followed by edema [15]. In sepsis, interleukin-6, interleukin-8, and tumor necrosis factor-α have been found to interact with the capillary endothelial cells and trigger edema of the bowel wall. When hypotension occurs due to reflex vasodilation and fluid retention in the third compartment, physicians use fluid resuscitation to compensate for the fluid sequestration. This, in turn, aggravates the changes in hydrostatic and oncotic pressures, worsening the interstitial fluid extravasation, while the upward compression of the diaphragm limits respiratory movements, increases central venous pressure, and finally, contributes to the potential risk of developing ACS. This sequence is not solely applicable to sepsis originating from a non-traumatic medical condition but should be kept in mind when caring for a trauma patient with a penetrating abdominal wound, which perforated a hollow organ such as the digestive tract and spread germs in the abdominal cavity
[14].

Otherwise, the typical polytrauma patient presents with one or multiple bleeding sources, potentially developing hemorrhagic shock within minutes-hours of the traumatic event. In this situation, a massive amount of fluid resuscitation may be necessary for the survival of the patient, either by blood transfusions or crystalloid resuscitation. Apart from the capillary leak syndrome and interstitial edema, the attempt to restore the effective circulating volume after an important ischemia-inducing blood loss will result in an ischemia-reperfusion injury to the bowel wall and increased capillary permeability. Crystalloid solutions will decrease the oncotic pressure, further aggravating the pressure imbalance and increasing the fluid extravasation and ultimately, IAP [14]. A trauma patient who, besides the initial injury, develops a condition that further aggravates his state, is a patient who suffers from the "second-hit" phenomenon. This phenomenon corresponds to neutrophil priming, which means that activated neutrophils (from the traumatic injury mechanism) are overstimulated by a subsequent mechanism, most often inadequate fluid resuscitation, and therefore have an exaggerated immune response and determines a massive cytokine release, which leads to ACS and MOF (multiple organ failure). The most vulnerable window of time for this phenomenon also matches the most frequent timeframe of occurrence of the ACS, the first 3-6 hours after the traumatic event [6].

Nevertheless, elevated IAP induces cardiovascular, neurological, hepatic, and renal dysfunction [6,10-14,16]. An increase in IAP exerts pressure on the inferior vena cava, resulting in a decrease in venous return to the heart and a reduced preload. By reducing the preload of the heart, the cardiac output is also decreased aggravating cellular hypoxia and generating crucial amounts of lactic acid which, combined with the respiratory acidosis induced by the restricted movement of the diaphragm and the ventilatory impairment caused by atelectasis, result in worsened cellular function. The respiratory function is also hindered by increased intra-thoracic pressure, increased pleural pressure, and decreased dynamic and static compliance [10]. Moreover, the decrease in blood flow translates into reduced renal perfusion and potentially acute kidney injury (AKI). The renin-angiotensin-aldosterone hormone system (RAAS) is activated when renal hypoperfusion stimulates renin secretion by the juxtaglomerular cells. Angiotensin II is a potent vasoconstrictor that increases peripheral vascular resistance and activates aldosterone secretion from the adrenal glands. Aldosterone, in turn, induces sodium and water retention, intending to increase renal perfusion, but fails to stabilize the mean arterial pressure (MAP) [11]. One study reports that the onset of oliguria may announce the debut of ACS [17]. The liver is also affected by increased IAP, even at a moderate elevation of 10 mmHg [10], and impaired liver function translates into a decreased serum lactate clearance [12]. Finally, elevated IAP increases intracranial pressure and therefore decreases cerebral perfusion pressure due to a domino mechanism initiated by the cephalad displacement of the diaphragm and elevation of the intra-thoracic pressure, accompanied by a reduced cardiac output.

Risk factors

Throughout time, the scientific world has shown great interest in the most important risk factors for IAH/ACS. Finally, in 2013, the WSACS [4] summarized them and created 4 categories divided by mechanism and a 5th additional miscellaneous group: diminished abdominal wall compliance, increased intra-luminal contents, increased intra-abdominal contents, capillary leak/fluid resuscitation, and others. In the first group, identified risk factors were found to be major trauma, major burns, abdominal surgery, and prone positioning among several studies. An increase in intra-luminal contents was suggested particularly in gastroparesis and ileus, while fluid collections in the abdominal cavity, acute pancreatitis, and sepsis were responsible for an increase in intra-abdominal contents. Acidosis was prevalent among risk factors in multiple studies, as well as massive fluid resuscitation, while others suggested hypothermia, damage control laparotomy, or poly-transfusion as a possible mechanism of capillary leak. An increased APACHE-II or SOFA score was also associated with a risk of developing ACS, as they are typically present in a critically ill patient. Other factors taken under consideration were age, increased HOB angle, obesity and increased BMI, mechanical ventilation, and positive end-expiratory pressure (PEEP) > 10. Shock, hypotension, and sepsis were also proposed.

In comparison, Holodisnky et al. [18] observed a noteworthy clinical heterogeneity and ambiguity between the studies that reported risk factors in ACS and aimed to address this crucial impediment by identifying evidence-based risk factors for particular patient populations. Therefore, the authors conducted a systematic review and meta-analysis in which potential risk factors were investigated (38 for IAH and 24 for ACS) and separated into three categories: patient characteristics, systemic physiology, and fluid resuscitation. In addition to those mentioned by Kirkpatrick et al. [4], this systematic review and meta-analysis included, among others: gender, white blood cell count, amylase, calcium, C-reactive protein and albumin level, Glasgow Coma Scale score, Ranson score for acute pancreatitis, cardiac index, serum creatinine level and urine output, blood glucose, base deficit, hemoglobin and hematocrit, pre-ICU and pre-hospital crystalloid, crystalloid to packed red blood cell ratio. Nevertheless, this study concluded that large-volume crystalloid resuscitation and the presence of shock/ hypotension were commonly found in all patient populations, while others were specific to a particular group. The trauma patient population associated a higher prevalence of pre-ICU crystalloid resuscitation, base deficit ≥12, and abdominal surgery as risk factors. In addition, hypothermia (temperature ≤ 34°), urine output ≤ 150 ml in 24 hours, hemoglobin ≤ 80 g/L, and $GAPCO_2 \geq 16$ were strongly associated with the development of ACS in the trauma patient group. Another relevant finding was that, as the volume of crystalloid used for resuscitation increased (≥ 7.5 L), the risk of ACS increased as well, with an Odds Ratio of 166.2 (CI 95%).

Head of bed elevation/patient positioning

Concerning the head of bed angle, a study published in 2009 by De Keulenaer et al. [19] raises the concern of a patient's position interfering with IAP measurement. The patients in the ICU may need to be nursed at a head-of-bed elevation of 30-45° to reduce the risk of ventilator-associated pneumonia and pressure ulcers, and this semi-recumbent position has been found to increase IAP by up to 4-9 mmHg, due to the viscera descending and exerting external pressure over the bladder. Furthermore, it has also been suggested that keeping a patient with a higher risk of developing IAH/ACS in a semi-recumbent position might trigger ACS [19]. In comparison, prone positioning has been demonstrated to elevate IAP, although the exact effects imposed on systemic and hepato-splanchnic blood flow or gastric-mucosal arterial PCO2 gradient have not been consensually established. This might be due to inaccuracies regarding the patient population taken under consideration and the type of mattress used for prone positioning [19]. Lastly, lateral positioning was analyzed in a small trial conducted by the same authors [20], in which De Keulenaer et al. concluded that out of the 10 patients included, the occurrence of IAP was 3.3% in the supine position and 26.6% in the lateral semi-recumbent position, which suggested that lateral decubitus may increase IAP by the same mechanism of visceral-induced external pressure on the bladder. A noteworthy limitation, besides the small study group, is that the trial only addressed patients with a low baseline IAP level, deeming it unreliable for the trauma patient population, in which a higher IAP level may be expected. Therefore, while the head-of-bed elevation effect on IAP has been established, further research on prone and lateral positioning is due. These findings are consistent with a study published by McBeth et al. [21] in 2007, in which a statistically significant relationship between a head of bed elevation of 30-45° and increased IAP was found.

Smit et al. [11] address these concerns in their study, proposing a reference table that can be used to correct IAP values depending on the head of a bed elevation. Their paper suggested that, for a head of bed angle between 0-20°, the measured IAP is correct and does not need any adjustment. Otherwise, for a head of bed elevation of 20-40°, the correct pressure is obtained by subtracting 4 mmHg from the measured IAP, while a head of bed angle greater than 40° requires subtraction of 9 mmHg from the measured value.

Fluid resuscitation

Fluid resuscitation is a vital part of therapy for trauma patients, given the fact that the most prevalent cause of death in the Early stage (first 72 hours after the traumatic injury) is hypovolemic shock due to blood loss [22,23]. Post-injury ACS is most frequently associated with inadequate fluid resuscitation of trauma patients [6]. Parenteral solutions used for fluid resuscitation are classified according to their molecular volume in crystalloids and colloids. Crystalloids include isotonic saline solution, Ringer's lactate, and hypertonic saline solution (contains larger quantities of sodium than the physiological concentration). Colloids, such as albumin, hydroxyethyl starch, and dextrans, have higher molecular weight and therefore generate an osmotic effect. Although rapid fluid resuscitation was widely considered the standard approach to hypovolemic shock in trauma patients [22], significant concern has been raised by some clinicians regarding the safety of the fluid resuscitation protocols. Hence, several studies addressed the issue: in a 2007 retrospective study, Madigan et al. [24] evaluated 48 patients with severe extremity injury who developed secondary ACS after trauma and compared them to a control group of patients who did not develop ACS. The authors concluded that the ACS group had received significantly higher amounts of crystalloid and blood products during all stages of care: pre-hospital, Emergency Department resuscitation, and post-admission hospital course. Therefore, early aggressive resuscitation by large volumes of crystalloids was found to be an important predictor of secondary ACS in the trauma patient population. This conclusion adheres to the reasoning of Balogh et al. [25] who suggested in 2003 that supranormal resuscitation (oxygen delivery index > 600 ml/m² achieved by a greater amount of crystalloid and packed red blood cell transfusions) was associated with an increased risk of IAH, ACS, MOF, and death.

In a 2012 multicenter prospective cohort study, Neal et al. [26] analyzed the crystalloid to packed red blood cell ratio (C:PRBC ratio) in a 452 patients population, only including those who needed ≥10 units of PRBC in the first 24 hours and survived past the initial 24 hours post-injury. The study population was divided into 2 groups by the C:PRBC ratio median: HIGH C:PRBC and LOW C:PRBC. The authors discovered that high ratios of C:PRBC (> 1.5:1 crystalloid to PRBC) were linked to a greater risk of MOF, ACS, and ARDS (Acute Respiratory Distress Syndrome) and this relationship was dose-dependent.

In 2015 Kaplan et al. [15] noted that excessive use of crystalloids causes dilution coagulopathy and hypothermia (if used un-warmed) and is therefore involved in triggering the "deadly triad" of acidosis, hypothermia, and coagulopathy. Hypertonic saline was found to be a valid alternative to colloids for increasing plasma osmolarity and also a better option than isotonic saline because of the ability to rapidly raise blood pressure without the need for a large volume of administration. Colloids, such as hydroxyethyl starch (HES), although useful for their osmotic effect of keeping fluid in the vessel, could be dangerous because of adverse effects and should only be used for a short time (< 24 hours) and respecting the resuscitation endpoints. The results of this study were that aggressive fluid resuscitation with isotonic crystalloid solutions may exacerbate the capillary leak syndrome and generate peripheral tissue edema, ascites, and IAH/ACS and that a valuable alternative could be hypertonic saline. HES should be avoided in the event of burns or sepsis. Finally, the implication of exaggerated fluid resuscitation in the pathogenesis of post-injury ACS was sustained by various other studies [8,27-30] and further emphasizes the importance of resuscitation endpoint criteria, awareness, and early recognition of IAH and ACS.

The "lethal triad" of acidosis, hypothermia, and coagulopathy

The "lethal triad" of acidosis, hypothermia, and coagulopathy is a catastrophic appearance in the management of trauma and is a result of fluid sequestration, hypoperfusion of vital organs, development of ischemia and lactate release in the bloodstream, along with systemic inflammatory response syndrome and the association of supranormal fluid resuscitation [31]. Stawicki et al. [32] note that ACS is a consequence of the "lethal triad" and should be prevented by Damage Control Laparotomy (DCL), which consists of a planned surgical approach with 3 steps: firstly, an abbreviated surgery should be implemented to control the active bleeding and limit the risk of sepsis. The abdomen should be partially covered and not closed, for example using a Bogota bag. Additional re-explorations may be necessary to drain potentially forming fluid collections (continued bleeding, pus, bile). The second step comprises ICU management with physiological restoration by correcting base deficit and coagulopathy, warming-up procedures, and continuing fluid resuscitation. When the patient is stable enough, the third step is implemented: definite surgical treatment which addresses, for example, bowel continuity restoration, and finally, the abdomen is closed.

Ditzel et al. [33] recently suggested that hypocalcemia is also an important predictor of mortality among trauma patients and should be included among the "lethal triad", forming a "lethal diamond". The authors described an intricate mechanism in which hypocalcemia is both a consequence and a promoting factor in the development of coagulopathy and acidosis: as serum calcium decreases, the calcium-dependent clotting factors become unfunctional and coagulopathy occurs; lower levels of serum calcium are linked to metabolic acidosis; hydrogen can competitively block ionized calcium receptors necessary for clotting; hypothermia decreases the liver function and therefore the liver is deemed unable to metabolize the citrate that is derived from transfusions; finally, ionized calcium is necessary for the proper function of cardiac myocytes and the lack of calcium is associated with significantly reduced cardiac contractility and decreased cardiac output, hypoperfusion, ischemia, and lactate production by hypoxic cells. Since the majority of trauma patients are hypocalcemic before receiving blood products and transfusions exacerbate the ionized calcium deficit, the authors concluded that calcium product administration for trauma patients requiring transfusions should be taken under consideration for further studies.

Damage Control Laparotomy

A mixed, retrospective, and prospective study conducted at a level 1 trauma center by Ertel et al. [34] demonstrated a clear association between Damage Control Laparotomy (DCL) and ACS. 311 patients with severe abdominal or pelvic trauma were included in this study and needed DCL for their injuries and 17 of them developed ACS, resulting in a 5.5% incidence, compared to the 14% obtained by Meldrum et al. [30]. Ertel et al. further noted that the association of both pelvic and abdominal trauma was remarkably more often linked to the development of ACS at a higher speed (the first 4-5 hours after trauma) compared to those who only presented abdominal or pelvic trauma [34]. The crucial discovery of this study is the fact that all the patients who developed ACS had had primary closure of the abdomen after the initial exploratory laparotomy. Set site by side, the patients that were treated with mesh closure of the abdomen did not develop ACS. This discovery suggests that primary fascial closure of the abdomen is an important risk factor for ACS in the surgically managed trauma patient population.

2 years later, Gracias et al. [35] analyzed this issue to a greater extent and conducted a retrospective review to discover whether or not the management of the open abdomen with temporary abdominal closure could prevent ACS and if there were any predictors of ACS in the patients treated with an open abdomen. A comparison was made between the 5 patients treated with temporary abdominal closure by vacuum pack who developed ACS and the other 15 patients who underwent the same treatment but did not develop ACS. Although base deficit levels, pH, and lactate levels on surgical ICU admission notably deteriorated in the ACS group, systolic blood pressure, prothrombin time, and temperature were similar between the 2 groups. Regrettably, no statistically significant relation between these potential predictors and the development of ACS could be made. Nevertheless, the mortality rate was remarkably higher in the ACS group (60%) compared to the non-ACS group (7%), further supporting the theory that ACS is an important predictor of mortality.

Shock/hypotension

Hypovolemic shock is most commonly seen in trauma patients as a result of acute hemorrhage, both internal and external. It can also be derived from massive fluid sequestration in the abdominal cavity, bowel wall, and interstitium due to increased hydrostatic pressure and decreased oncotic pressure in plasma, as seen in SIRS. The consequences are diminished effective circulatory volume, decreased cardiac output, and reduced perfusion to vital organs, including the kidneys and brain. The severity of hypovolemic shock varies from mild (less than 20% of total blood is lost) to severe (>40%) and depends not only on the volume of the blood loss but also the rapidity of which it is produced and the age and comorbidities of the patient [22]. Hypovolemic shock requires fluid resuscitation and blood products, but the endpoint of resuscitation is vital for avoiding a catastrophic complication: ACS. One must be aware of the hemodynamic criteria [36]: central venous pressure (CVP) between 8 to 12 mmHg in the first 6 hours of resuscitation, mean arterial pressure (MAP) > 65 mmHg, central venous oxygen saturation ($ScvO_2$ > 70%) and transthoracic echocardiography (TTE) inferior vena cava diameter > 20 mm.

Interestingly, Schreiber et al. [36] proposed, in a prospective randomized pilot trial that permissive hypotension might be beneficial for traumatic injury survivors. Eligible patients (out-of-hospital systolic blood pressure SBP ≤ 90 mmHg) were randomized and assigned into 2 groups: those who received controlled resuscitation, meaning 250 ccs of crystalloid in the absence of radial pulse or SBP < 70 mmHg and additional 250 cc boluses to maintain radial pulse or SBP ≥ 70 mmHg and those who received standard resuscitation, which consisted in 2 liters of fluid initially and additional fluid as needed to maintain SBP ≥ 110 mmHg. The controlled resuscitation strategy ultimately associated a decrease in early crystalloid use by 1 liter and an increase in early blood products use, adhering to the Damage Control Resuscitation (DCR) philosophy of permissive hypotension until hemorrhage control and a therapeutic plasma:platelets: PRBC ratio of 1:1:1. Although there were no statistically significant differences regarding mortality rate at 24 hours between standard and controlled resuscitation groups, improved mortality in blunt trauma patients was detected.

Duchesne et al. [15] also evaluated whether or not permissive hypotension was ultimately helpful for trauma patients who suffered a massive hemorrhage. The potential benefit suggested by former articles was that a slightly reduced arterial pressure could limit the amount of ongoing hemorrhage and therefore buy some time to allow surgical control of the bleeding. The authors raised concerns regarding the appropriateness of this practice in the general trauma population, the absence of a lower systolic or mean arterial pressure safety limit and the disastrous effects of severe traumatic brain injury. Hence, permissive hypotension is not currently recommended by the guidelines and should be further analyzed.

Retroperitoneal hematoma

In 2009, He et al. [37] suggested an increased prevalence of secondary ACS after pelvic fractures, due to an expanding retroperitoneal hematoma or the fluid resuscitation needed to compensate for the blood loss associated with this particularly severe type of fracture. Although the multivariable regression model showed that for each 1L of resuscitation fluid administered over 24hrs there was an expected 5 mmHg elevation of IAP ($p = 0.002$), no statistically significant correlation was found between pelvic fractures and IAP ≥ 12mmHg. Cook et al. [38] also approached the subject in 2002 and consequently demonstrated that the patients who suffered a rotationally or vertically unstable pelvic fracture were at a higher risk of developing resistant hypotension that could only be resolved by angiographic embolization. Agri et al. [39] later indicated that type C pelvic fractures were associated with a higher mortality rate and a greater rate of packed red blood cell (PRBC) transfusion than type B and A fractures. More research is necessary for the future to inform a possible correlation between pelvic fractures and ACS.

Although retroperitoneal hematomas are most frequently encountered after pelvic fractures, there are other possible causes. Beckman et al. [40] mentioned the implication of ruptured abdominal aortic aneurysms in the occurrence of retroperitoneal hematomas. The ongoing hemorrhage expands the hematoma and increases IAH, resulting in the development of primary ACS, hence this is considered a surgical emergency. The surgical approach to a ruptured abdominal aortic aneurysm can be endovascular (EVAR) or open (laparotomy). Dayama et al. [41] analyzed 352 patients who suffered from a ruptured abdominal aortic aneurysm following polytrauma and compared the efficiency of two different treatment options. 91 patients underwent endovascular repair and the remaining 234 patients were treated with an open aortic repair. Albeit the overall mortality rate was remarkably high (up to 51.7% during admission), the authors discovered that endovascular repair was associated with a decreased mortality rate (20.9%, p-value < 0.001) compared to the open abdominal approach (63.7%). An important downside of the endovascular approach is the possibility of post-repair ACS. In a systematic review and meta-analysis, Oliveira-Pinto et al. [42] reported a 9% incidence of ACS after endovascular repair of ruptured abdominal aortic aneurysms, as a result of an important retroperitoneal hemorrhage that could not be properly addressed without open surgery.

Demographics: age, gender, and race

None of the studies taken under consideration demonstrated any statistically significant relationship between demographic factors such as age, gender, or race and the development of IAH/ACS.

CONCLUSION

ACS is a significantly threatening condition for the trauma patient population. To summarize, many potential risk factors were evaluated for the envisagement of the present paper, but the ones that prevailed the most were excessive fluid resuscitation, shock/hypotension, retroperitoneal hematomas, and the “lethal triad”. Consistent with other studies, no connection was found between age, gender, or race and the development of ACS. Further studies should focus more on the likely involvement of damage control laparotomy and patient positioning, as well as hypocalcemia, in the unfolding of ACS in trauma patients.

Social and psychological predictors of alcohol-related incidents involving servicemen

Yanina Matsegora[1], Oleksandr Kolesnichenko[1], Ihor Prykhodko[1], Olena Kravchenko[2], Vitalii Kyslyi[3], Maksym Bayda[1], Nataliya Kryvokon[2], Yurii Rumiantse[4], Kateryna Marushchenko[4], Andrii Pashchenko[2]

Abstract: *The aim of the research was to determine the social and psychological predictors of alcohol-related incidents involving servicemen. The research involved 310 servicemen, who were subjected to disciplinary and administrative penalties within 2016-2021 years for the offence commitment under the influence of alcohol. The control group included 650 servicemen who joined the service within this period. The analysis of psychological features of servicemen was carried out with the help of the following methods: "Determination of Type Accentuation of Character Traits and Temper" Questionnaire, "Self-Esteem Structures of Temper Questionnaire", "Multilevel Personality 'Adaptability' Questionnaire", "Progressive Matrix", "16 PF Questionnaire", and "Self-Esteem Structures of Temper Questionnaire". Cluster analysis was used to differentiate servicemen who committed incidents under the influence of alcohol. The determined typology was valuable for the organization of preventive works, events dedicated to the improvement of socialization by recruits, adequate formation of servicemen image as well as their identification in accordance with it, and events dedicated to the prevention of suicidal behaviour.*

Keywords: *incidents under the influence of alcohol, servicemen, adequate behaviour, preventive psychology*

INTRODUCTION

The use of alcohol by servicemen was a problem for numerous armies all over the world. Unpleasant statistics concerning the alcohol abuse was highlighted by the researchers from Australia [1], Great Britain [2-3], France [4], and the USA [5]. They proved that alcohol abuse did not only have negative effect on the servicemen's health, wellbeing, moral state, the effectiveness of their military activity, and on readiness to complete missions, but also had financial losses because of alcohol-related accidents (ARIs). The researchers proposed the program of alcoholism prevention for army in general as well as for communities where the military units were located. Other researchers such as Grattan, Mengistu, Bullock, Santo, & Jackson [6] determined that the prohibition to sell alcohol beverages to servicemen at night had positive influence on the statistics of the crime level in definite community.

The research of recent years demonstrated that the military service was joined mostly by school leavers who were drinking alcohol beverages but not by those who did not have such obsession [7]. Other researchers such as Shirvani, Reed, Clingan [8], and Lamb, & Baron [9] distinguished the connection between the alcohol abuse by youth from 24 to 32 years old and military personnel. In accordance with their works servicemen drank alcohol because that was the part of military culture.

Another group of scientists Hunter, Talcott, Klesget, Lando, & Haddock [10], Jeffry, & Mattiko [11] pointed out that there was a close link between the alcohol abuse and tendency to risky behaviour by male servicemen as well as by female ones.

Traditionally, high level of alcohol abuse by servicemen was caused by experienced stress during the participation in combat operations and their negative consequences

including post-traumatic stress disorder (PTSD) [12]. In accordance with the research conducted by Jones and Fear [13] the increased number of cases of alcohol abuse related to negative experience which was caused by transition from combat operations to civil life.

Ong and Joseph [14] pointed out that unexperienced servicemen of junior management who served abroad on long-term business trips (they used to long separation from their families, friends, resources' limitation, high level of combat readiness, and limited local jurisdiction, etc.) were the most vulnerable part. They chose negative copings including alcohol abuse.

Bartone, Hystad, Eid, & Brevik [15] studied psychological hardiness and avoidance of coping as predictors of risk for alcohol abuse in military personnel following war-zone deployment. Their results showed that low level of psychological hardiness, more combat exposures, younger age, and lower rank were associated with increased risk for alcohol abuse soon after the return from deployment. At follow-up, avoidance of coping was a significant predictor of risky alcohol abuse.

Skipper, Forsten, Kim, Wilk, & Hoge [16] examined the association between specific combat experience and post-deployment hazardous drinking patterns of selected military personnel that was considered to pose high risk, such as personnel belonging to the U.S. Army Special Operations Forces. In their study, combat experience was divided into the following categories: (1) Fighting, (2) Killing, (3) Threat to oneself, (4) Death/Injury of others, and (5) Atrocities. They determined, that combat experience related to fighting, threat to oneself, and atrocities was significantly connected with alcohol abuse being analyzed individually. However, when the factors were examined simultaneously, combat experience in the fighting category was significantly associated with a positive screen of alcohol abuse. In conclusion, soldiers who belonged to certain elite combat units were more likely to screen positive of alcohol abuse if they were exposed to specific types of combat experience versus any other type of combat exposure.

Other researchers such as Russell, Russell, Riviere, Thomas, Wilk, & Bliese [17] distinguished that among the participants of the research there increased the quantity of use of alcohol up to 80.5% while alcohol abuse increased from 8.51% to 19.15%. However, alcohol abuse among those who killed enemy during the combat significantly decreased.

Hoopsick, Homish, Collins, Nochajski, Read, & Homish [18] having compared servicemen of the National Guard of the USA who took part in combat operations with those who did not have such experience distinguished that low resilience and existence of psychological problems due to this situation became the reason of addictive behaviour of servicemen, but not the participation in combat operations.

Hanwella, de Silva, & Jayasekera [19] compared the reasons of alcohol abuse by servicemen of Great Britain and the USA with servicemen of Sri Lanka Navy's Special Forces where the tradition of alcohol abuse among the citizens in general significantly differed from the traditions of alcohol abuse in Great Britain and the USA. They pointed out that the high level of alcohol abuse during combat operations was connected with worsened psychological health and functional disorders of servicemen of Great Britain and the USA, but that was not diagnosed with servicemen of Sri Lanka. The authors concluded that the alcohol abuse was significantly influenced by national traditions of the country where they served which included the features related to alcohol accessibility and attitude to alcohol.

McCabe, Watrous, & Galarneau [20] said that 49% of servicemen who were wounded in past even 10 years later had positive screening on PTSD and depression. The participants of this research had high level of alcohol abuse, problems of tobacco and cigarette use, lack of sleep as well as physical activity.

Other researchers such as Boscarino, Hoffman, Pitcavage, & Thomas [21] figured out that group of veterans who were on outpatient care where the majority were veterans of the Vietnam War (72%) among this group 9.6% had eternal PTSD, 18.4% had eternal depression, and 50.1% had eternal consultations with the service of psychological aid. Among the key factors which were connected with PTSD, depression, and a need to use the service of psychological aid they pointed out low self-esteem, alcohol or drug abuse to overcome histories of childhood trauma, high level of combat influence, and low psychological resilience.

Angkaw, Haller, Pittman, Nunnink, Norman, Lemmer, McLay, & Baker [22] distinguished that the veterans who returned from Operation Enduring Freedom and Operation Iraqi Freedom (OEF/OIF) were found to be at increased risk for post-traumatic stress disorder (PTSD) and alcohol abuse disorders, leading to negative mental health–related quality of life (MHRQoL).

Recent research conducted by Derefinko, Hallsell, Isaacs, Salgado Garcia, Colvin, Bursac, McDevitt-Murphy, Murphy, Little, Talcott, & Klesges [23] demonstrated that the separated transition from active duty to civilian life could become critical in terms of the future functioning of the veteran. Repeated estimating tests indicated that endorsement of alcohol abuse, cigarette abuse, and prescription of drug abuse was similar during active duty and dismissal; marijuana and hard drugs abuse significantly increased in the 6-month period of dismissal. Active-duty of anxiety/depression and aggressive feelings were maintained from active-duty to dismissal, loneliness and military-based trauma symptoms increased significantly as well.

Kintzle, Oh, Wilcox, Hassan, Ell, & Castro [24] figured out that post-deployment civilian unemployment became a common problem and source of additional stress for the National Guard (NG) personnel. Alcohol abuse was concluded to moderate the relationship between civilian unemployment and mental health symptoms.

Since the problem of alcohol abuse happened to servicemen within the whole period of service starting with the entrance and finishing with dismissal (even in civil life after the dismissal), modern research was aimed at the search of predictors which could give possibility to decrease the quantity of servicemen who had potential tendency to alcohol abuse during their service including combat operations.

Hunter et alia [10] examined demographic, lifestyle, and psychosocial variables to determine predictors of the Air Forces recruits who were likely to have alcohol-related problems. The study involved the recruits of the Air Forces (N = 32 144), who underwent basic training from August 1995 to September 1996. They determined that psychosocial predictors included positive rebellious attitudes, decreased seatbelt use, and positive risk-taking attitudes.

The research conducted by Sarramon, Vendoux, Schmitt, & Bourgeois [25] demonstrated that susceptibility to boredom, impulsiveness, and search of thrills as well as adventures could increase the possibility to gain adequate behaviour.

Gutierrez, Blume, Schmaling, Stoever, Fonseca, & Russell [26] considered that identifying the predictors of alcohol consequences which occurred upon demobilization could help in determining which soldiers were at risk for such consequences before deployment and could help to maintain military readiness. They identified that significant predictors of greater alcohol-related incidents, included less quantity of years of formal education, male gender, non-engagement in an intimate relationship, racial/ethnic minority status, enlisted rank, deployment to the continental United States, and greater stress, whereas significant predictors of drinking and driving included male gender, non-engagement in an intimate relationship, and greater stress.

There was a need to point out that researchers Selman et alia [1], Henderson et alia [2], Iversen et alia [3], Ong et alia [14], and Bartone et alia [15] determined that young age as well as low rank were social and demographic predictors of alcohol abuse of servicemen. That, in turn, turned urgency to the topics such as victimization and unfair attitude as the cases of alcohol abuse.

Other researchers Ames, Moore, Cunradi, Duke, & Galvin [27] identified interrelationships of unfair treatment at work, stress, and problem drinking among a sample of the U.S. In their research, it was found that more women than men (51.4% versus 16.2%) reported gender unfair treatment; approximately 20% of respondents reported ethnic/racial unfair treatment. The researchers concluded that unfair treatment was associated with likelihood of problem drinking, but associations were attenuated after adjusting for frequency of work problems and expecting alcohol to alleviate stress.

Kim Y, Kim J, Park, & Fear [28] investigated workplace victimization as a cause of alcohol abuse in junior military personnel (JMP). Workplace victimization in JMP was prevalent (17.7%). Victims in the workplace showed higher level of anger and alcohol abuse. In mediation analyses, workplace victimization was related to higher levels of anger, which, in turn, were associated with greater alcohol abuse.

In addition to the interrelationships and mediators the researchers Benjamin, Bell, and Hollander [29] resorted to the determination of the typology in the process of examining the problems of alcohol abuse by servicemen. This allocation of subgroups gave the possibility to figure out the tendencies for drinking alcohol which were inherent in servicemen. It could help to prevent alcohol abuse [4] or could become additional factor to diagnose suicidal risks of servicemen [5].

MATERIALS AND METHODS

Participants and Procedure

This research determined the social and psychological predictors which were based on the generalization of data concerning the professional psychological selection of servicemen who committed ARIs. This research had retrospective character. Received results could help to improve professional psychological selection for service and could help to differentiate the approaches for the events based on prevention of alcohol abuse.

This research involved the servicemen who were prosecuted to disciplinary and administrative penalties for committed offences under the influence of alcohol (310 individuals). As the control group there were presented the servicemen who joined the military service within this period of time (650 individuals).

Instruments and Measures

The results of psychological selection of candidates for the service were used to determine the types of servicemen who committed alcohol-related incidents. A range of psychological tests included several questionnaires implemented in electronic form for testing and processing the results obtained in the Automated Psychodiagnostic Complex (APC), called "Psychodiagnostics" in short form [30].

To determine the characteristics of personality temper there was used the "Self-Esteem Structures of Temperament Questionnaire" (Smirnov, as cited by Vorobyova et alia) [30].

Determination of character traits which worsened the process of adaptation to new conditions and reasons of life was formed with the questionnaire "Determination of Type Accentuation of Character Traits and Temperament" (DTACTT; Schmieschek, as cited by Vorobyova et alia) [30]. In the basis of this questionnaire there was the theory of character accentuation developed by Leonhard (as cited by Vorobyova et alia) [30]. In accordance with this conception specific character traits were divided into two groups such as main and additional. The core of individual was in the basis of main traits of a person. These traits were: individuality, development, adaptation, and psychological health. Excessive expression of these traits led to structural psychological changes and in hostile environment to the development of individual's structure.

General skills of servicemen were figured out with the "Progressive Matrix" test (Raven and Raven) [31]. Results based on this test provided us with information on the abilities of servicemen to get definite forms, to take their personalities, temper and mutual relations or ensemble as well as combination of relations.

The specificity of motivation of choosing the profession of a serviceman was determined with the "Questionnaire on Examination of Professional Selection Motivation" (Moskalenko, Kobzin, & Starodubtsev, as cited by Vorobyova et alia) [30].

General information about character traits which were formed throughout the candidates' life was obtained with the "Sixteen Personality Factor Questionnaire" (16-PF Questionnaire, as cited by Vorobyova et alia) [30].

Among the examined group of servicemen who committed ARIs there were distinguished the groups for comparison with the help of cluster analysis. As a criterium of segmenting there were used the scales of the method "Multilevel Personality 'Adaptability' Questionnaire" (MPAQ; Maklakov and Chermyanin) [32] that gave the possibility to provide the analysis with the summarized estimation of the specificity of the individual's adaptation to new conditions and of the tolerance to its changes.

Data Analysis

A cluster analysis was used to compare the data of psychodiagnostic scales in studied groups. To represent the data, we used the main descriptive statistics (arithmetic mean – M – and standard deviation – SD). To reliably detect significant differences between comparative groups, there was used the t-Student criterion. Mathematical data were processed through SPSS 17.0.

RESULTS

In comparison with the control group servicemen who committed ARIs were less motivated, active, and capable to rapid mobilization of strength. The indicators of personal peculiarities of servicemen who committed ARIs were proposed in Table 1.

The indicators of peculiarities of servicemen who committed ARIs in comparison with the control group were proposed in Table 2.

The indicators of distinctions' significance of servicemen who committed ARIs in comparison with the control group were proposed in Table 3.

In accordance with almost all the scales of close questionnaire "Studying the Motivation of Professional Choice by Applicants of Higher Educational Institutions of the Minister of Internal Affairs of Ukraine" servicemen who committed ARIs had the lowest indicators of the "Motives Connected with Objective Socially Set Aims and Content of the Profession" ($t= 5.18$, $p \leq .01$), "Motives Connected with Personal and Professional Development" ($t= 5.67$, $p \leq .01$), "Independent Professional Choice" ($t= 3.23$, $p \leq .01$), "Motives Connected with External Prestige of Profession and Material Wellbeing" ($t= 5.71$, $p \leq .01$), "Motives Connected with Romantic Appeal of Profession" ($t= 4.97$, $p \leq .01$), "Motives Connected with Eagerness to Compensate the Characterological Weaknesses" ($t= 7.31$, $p \leq .01$), "Antisocial Motives" ($t= 4.67$, $p \leq .01$). Lower indicators of Types of Accentuation were distinguished due to the method "Determination of Type Accentuation of Character Traits and Temper" – "Hyperthymic" ($t= 5.39$, $p \leq .01$) and "Exalted" ($t= 2.75$, $p \leq .01$). Servicemen who committed ARIs, due to the method "Self-Esteem Structures of Temper Questionnaire" were less extroverted ($t= 1.96$, $p \leq .1$). Due to the indicators of method "16 PF Questionnaire" they had the lowest indicators of conformism (t= 3.97, p ≤.01), practicality (t= 4.20, p ≤.01), sociability (t= 3.59, p ≤0.01), and intellect. These distinctions were expressed for intellect as general awareness (t= 3.40, p ≤.01) but not for general ability to study due to the method "Raven's Progressive Matrices" (t= 2.81, p ≤.01).

*Notes: CG= Control Group; ARIs= Alcohol-Related Accidents; A= Group A; B= Group B; C= Group C; 0 p ≤.1; * p ≤.05; ** p ≤.01; *** p ≤.001*

The majority of servicemen who committed ARIs were 50.32% of servicemen of enlisted personnel, 38.71% of non-commissioned and petty officers, and 10.32% of junior officers. The minority of servicemen of this group were senior officers – 0.65%. 2/3 of this group (66.45) were unmarried or divorced. 53.55% had experience of service which was not longer than 3 years, 29.68% had experience of service which was from 4 to 10 years, and 16.77% had experience of service which was longer than 10 years. 50.32% of servicemen had the status of participants in hostilities.

Even though all the servicemen who committed ARIs were characterized as those who had the decrease of the quality of interaction with surrounding substantive and social world (decrease of activity, adequacy, etc.) this group was not homogenous. There were determined the following groups A, B, and C after the use of cluster analysis (as a criterium of segmenting there were used the scales of the method "Multilevel Personality 'Adaptability' Questionnaire") among the servicemen who committed ARIs. The increase of the quantity of clusters of analysis gave the possibility to figure out the subgroups A1, A2, B1, B2, B3, and B4 within the groups A and B.

Despite other typical distinctions for servicemen who committed ARIs (the quantity was 12.16% from the analyzed group of servicemen who committed ARIs) group A differed from the control group with high level of sincerity due to the method "Multilevel Personality 'Adaptability' Questionnaire" – "Credibility" (t= 11.76, p ≤.01) and due to the method "Self-Esteem Structures of Temper Questionnaire" – "Sincerity" (t= 6.59, p ≤.01) and significantly higher indicators of disadaptivity on all the scales of the method "Multilevel Personality 'Adaptability' Questionnaire" – "Neuropsychological Resilience" (t= 2.46, p ≤.05), "Communication" (t= 6.91, p ≤.01), "Morality" (t= 5.79, p ≤.01), general indicator of "Adaptivity" (t= 5.75, p ≤.01). Due to the method "16 PF Questionnaire" the representators of group A in comparison with the control group had significantly lower level of self-esteem (t= 3.56, p ≤.01), emotional stability (t= 1.79, p ≤.1), and significantly higher level of conservatism (t= 1.82, p ≤.1), and subordination (t= 2.29, p ≤ .05).

Servicemen of groups B and C differed from group A due to the method "Multilevel Personality 'Adaptability' Questionnaire" with higher level of credibility (tA-B= 11.78, tA-C= 5.65, p ≤.01 for both values) and scales of the method "Self-Esteem Structures of Temper Questionnaire" – "Sincerity", (tA-B= 6.51, p ≤.01), "Morality" (tA-C= 1.91, p ≤.1). Due to the method "16 PF Questionnaire" they had the lowest indicators of Antisocial Motives (tA-C= 1.76, p ≤.1) and self-esteem (tA-B= 4.79, p ≤.01 and tA-C= 2.35, p ≤.05). However, group A due to the method "Progressive Matrix" had the highest indicators of IQ among the distinguished groups B and C (tA-C= 1.74, p ≤.1), which brought representators of group A closer to the control group.

Social and demographic data of group A was determined by the fact that 60% of this group had experience of service not longer than 3 years, they were the part of enlisted personnel and were divorced. A half of servicemen of this group had the status of participants in hostilities. About 40% of servicemen had experience from 10 to 25 years and were the participants in hostilities. A half of servicemen of group A were divorced.

The analysis of results gave the possibility to conclude that servicemen of group A experienced crisis of values, they highly regarded norms, rules of behaviour and understood their inconsistency. Such situation was a result of getting into new surrounding or of overthinking the values.

The increase of the quantity of clusters gave the possibility to determine two subgroups in group A (subgroup A1 – 72.22% and subgroup A2 – 27.78%). The indicators of significance of distinctions among the determined subgroups in group A were presented in Table 4.

*Notes: A= Group A; A1= Subgroup A1; A2= Subgroup A2; 0 p ≤.1; * p ≤.05; ** p ≤.01; *** p ≤.001*

Subgroups A1 and A2 differed with their level of the crisis of values. Thus, servicemen of subgroup A2 had significantly higher indicators of answers' sincerity – "Credibility" (t= 2.69, p ≤.05). There were higher indicators of disadaptivity due to the method "Multilevel Personality 'Adaptability' Questionnaire" – "Neuropsychological Resilience" (t= 2.72, p ≤.05), "Morality" (t= 6.59, p ≤.01), and "Adaptivity" (t= 5.22, p ≤.01). Results received due to the method "16 PF Questionnaire" demonstrated higher indicators of suspicion (t= 2.42, p ≤.05), radicalism (t= 2.65, p ≤.05) and lower indicators of normativity (t= 2.18, p ≤.05). Moreover, subgroup A2 in comparison with subgroup A1 due to the method "Self-Esteem Structures of Temper Questionnaire" had higher indicators of extraversion (t= 2.20, p ≤.05) and anxiety (t= 1.86, p ≤.1). Furthermore, representators of subgroup A1 due to the method "Progressive Matrix" were diagnosed with the higher indicators of IQ; however, those distinctions did not reach the level of statistical significance.

The analysis of the results gave the possibility to conclude that the problems of disadaptivity of subgroup A1 were connected with the process of understanding their own inconsistency to the norms which were unacceptable for the surrounding. Servicemen of subgroup A2 had a decreased ability to be led by norms, to control their reactions in accordance with them, had lower ability to entrust themselves to those rules. These peculiarities were caused by the age and lack of experience of self-regulation. Servicemen of subgroup A1 were enlisted personnel who had little experience of service (up to 3 years), moreover, 80% of them were divorced.

The indicators of personal peculiarities of servicemen who committed ARIs from group B were presented in Table 5.

Table 5: The indicators of personal peculiarities of servicemen who committed alcohol-related incidents within the subgroups of group B (in Standard Points)

Notes: B= Group B; B1= Subgroup B1; B2= Subgroup B2; B3= Subgroup B3; B4= Subgroup B4

Servicemen from group B (82.43% from the general quantity of servicemen who committed ARIs) differed from other groups of research with the lowest level of sincere questions due to the method “Multilevel Personality ‘Adaptability’ Questionnaire”. With their answers they tried to create socially approved image. Servicemen from group B in comparison with the control group had better indicators of adaptivity – “Neuropsychological Resilience” (t= 3.40, p ≤.01), “Communication” (t= 2.22, p ≤.05), “Morality” (t= 2.99, p ≤.01), and general indicators of “Adaptivity” (t= 3.96, p ≤.01). Besides the eagerness to gain social approval servicemen of group B as well as other representators who committed ARIs had decreased quantity of interaction with surrounding substantive and social world.

Group B included 4 subgroups: subgroup B1 constituted 14.75%, subgroup B2 constituted 18.85%, subgroup B3 constituted 26.22%, subgroup B4 constituted 40.16%. Indicators of significance of distinctions between the determined subgroups of Group B which were presented in Table 6.

Servicemen of subgroup B1 differed from other subgroups B2, B3 and B4 with the highest level of sincerity due to the method “Multilevel Personality ‘Adaptability’ Questionnaire” – “Credibility” (3.11±1.84), due to the method “Self-Esteem Structures of Temper Questionnaire” – “Sincerity” (9.17±4.08) and the highest level of intellect due to the method “Progressive Matrix” – “IQ” (107.56±11.71), “16 PF Questionnaire” – “Low-high intellect” (4.33±1.50). Besides that, those servicemen differed due to the method “Determination of Type Accentuation of Character Traits and Temper” with indicators such as “Hyperthymic” (18.67±3.79) and “Exalted” (11.67±3.83). Due to the data received with the method “16 PF Questionnaire” they were less predisposed to dominance

(5.28±1.49) and non-conformity (3.83±1.50). The results of the method “Self-Esteem Structures of Temper Questionnaire” showed that servicemen had high level of emotional stability (1.89±2.05).

Table 6: The indicators of significance of distinctions among the determined subgroups of group B (in Standard Points)

	T B1 – B2	T B1 – B3	T B1 –B4	T B2 – B3	T B2 – B4	T B3 – B4

The representators of subgroup B1 in comparison with the control group due to the method “Multilevel Personality ‘Adaptability’ Questionnaire” had better indicators of adaptive abilities: “Neuropsychological Resilience” (7.67±2.30), “Communication” (7.94±2.34), “Morality” (4.28±1.99), and general scale of “Adaptivity” (19.89±3.38). Due to the method “16 PF Questionnaire” they had higher level of self-esteem (9.94±2.01) and due to the method “Determination of Type Accentuation of Character Traits and Temper” they had high level of general activity (“Hyperthymic” – 18.67±3.79).

2/3 of the subgroup B1 had the status of participants in hostilities, 2/3 had experience of service from 3 to 5 years, a half of the subgroup was not married. Enlisted personnel, non-commissioned and senior officers were presented almost equally, and their quantity was about 45%, junior officers constituted about 10%.

Received results proved that servicemen of subgroups 2.1 were intellectually developed, active, and adaptive, they had professional and combat experience; however, they were not ambitious, did not see the possibility to realize themselves in profession as a serviceman and, probably, regretted their professional selection.

Servicemen of subgroup B2 among all the representators of group B due to the method “Multilevel Personality ‘Adaptability’ Questionnaire” had the highest level of disadaptivity: “Adaptivity” (35.35±3.81), “Neuropsychological Resilience” (17.87±3.27), “Communication” (11.09±2.41), except for “Morality” (6.39±1.78) which were the highest indicators among the representators of subgroup B4.

They differed from other subgroups of group B and the control group with more expressed indicators due to the method “Determination of Type Accentuation of Character Traits and Temper” – “Anxious-Fearful” (4.96±4.30), “Excitable” (6.65±3.94), and “Disthymic” (10.43±3.60), also they had lower indicators of “Hyperthymic” (13.96±5.32), “Demonstrative” (11.91±5.24), and “Exalted” (8.09±5.89). The representators of this group had the lowest indicators due to the scales of close questionnaire “Studying the Motivation of Professional Choice by Applicants of Higher Educational Institutions of the Minister of Internal Affairs of Ukraine” – “Motives Connected with Objective Socially Set Aims and Content of the Profession” (18.96±6.32), “Independent Professional Choice” (16.09±5.81), “Motives Connected with External Prestige of Profession and Material Wellbeing” (16.22±5.66), and “Motives Connected with Romantic Appeal of Profession” (14.30±5.79). Servicemen of subgroup B2 due to the method “16 PF Questionnaire” were more reserved (8.30±1.89), emotionally instable (8.78±1.91), anxious (4.70±2.20), had lower indicators of conformity (5.35±1.82) and normativity (7.48±2.78). Due to the method “Self-Esteem Structures of Temper Questionnaire” they had the highest indicators of emotional anxiety (3.91±3.93) and the lowest indicators of “Reaction Pace” (11.04±4.54) and “Activity” (16.13±8.04) which were the highest indicators among all other servicemen of group B.

Among the servicemen of subgroup B2 the majority (52%) was constituted by enlisted personnel with experience from 1 to 2 years. The quarter of servicemen had experience longer than 15 years. 2/3 of the representators were unmarried or divorced. More than a half of representators (56.52%) participated in hostilities. The officers of this subgroup constituted not more than 5%.

Received results gave the possibility to conclude that the representators of subgroup B2 tried to create the image of individual who due to the suffering could control themselves not so efficiently and had lower level of productivity. These servicemen tended to appeal to their negative experience as to excuses of their impertinence, unproductivity, and alcohol abuse.

The representators of subgroup B3 in comparison with all the groups and subgroups due to the results of the method "Self-Esteem Structures of Temper Questionnaire" were less sincere in their answers – "Sincerity" (3.78±3.46) and "Multilevel Personality 'Adaptability' Questionnaire" – (8.38±2.11). They described themselves as those who had the best indicators of adaptivity due to the method "Multilevel Personality 'Adaptability' Questionnaire" – "Adaptivity" (18.56±4.10), "Neuropsychological Resilience" (7.50±2.13), "Communication" (6.81±2.58), and "Morality" (4.25±1.63). Moreover, they had the lowest indicators of emphasizing due to the types such as: "Anxious-fearful" (1.69±2.74), "Cyclothymic" (7.69±2.15), and "Excitable" (3.75±2.53). They were extremely self-confident, had high level of self-esteem (11.19±1.65), calm (2.63±1.68), relaxed (2.78±1.79), self-controlled (8.25±1.24), and restrained (4.75±1.83). They trusted to the surrounding world (3.84±1.76), they were practical (4.44±2.05) and active (21.25±4.22).

About 60% of those servicemen had experience of service up to 3 years. 47% did not have any experience of participation in combat operation. 62.5% of servicemen of this subgroup were unmarried or divorced.

Therefore, servicemen of subgroup B3 abused alcohol because they demonstrated the role of experienced professional.

The representators of subgroup B4 differed from other subgroups with expressed disadaptivity related to the attitude to norms which regulated relations. They used the profession of serviceman to gain priority over other people. The representators had higher indicators due to the scales of questionnaire "Studying the Motivation of Professional Choice by Applicants of Higher Educational Institutions of the Minister of Internal Affairs of Ukraine" among which there were "Motives Connected with Objective Socially Set Aims and Content of the Profession" (22.04±4.33), "Motives Connected with External Prestige of Profession and Material Wellbeing" (18.53±4.26), "Motives Connected with Romantic Appeal of Profession" (16.71±4.57), "Motives Connected with Eagerness to Compensate the Characterological Weaknesses" (19.86±3.70), and "Antisocial Motives" (13.37±5.38). They had higher indicators of dominance (6.24±1.73). The representators of subgroup B4 due to the method "Self-Esteem Structures of Temper Questionnaire" had highly expressed extraversion (18.92±3.59) and higher indicators of reaction pace (13.33±3,47) than any other subgroup.

Only a quarter of servicemen of subgroup B4 was married. Almost a half of them had experience of service longer than 3 years. A quarter of servicemen had experience of service not less than 10 years. 47% of servicemen had experience of combat operations. Almost 43% of representators of this group were enlisted personnel, 45% were non-commissioned and petty officers, 12% were officers.

Servicemen of subgroup B4 wanted to dominate, to assert themselves at the expense of others, to achieve that they did not want to use physical strength, but their status and belonging to social group which was empowered. They wanted to become respectful people.

Group C (that was 5.4% from the general selection of servicemen with alcohol dependence) differed from other groups who committed ARIs and the control one with the highest indicators of general disadaptivity (59.00±5.40) which were mostly connected with low level of neuropsychological resilience (33.00±4.14) and communication (17.38±3.58), also they had slightly lower indicators of morality (8.63±1.19). Besides that, due to the method "Type of Accentuation of Character Traits and Temper" among all other groups they had the lowest indicators of "Hyperthymic Type" (14.63±5.88) and the highest indicators of "Anxious-Fearful" (7.88±4.52), and "Exalted Type" (14.25±5.50). Due to the method "16 PF Questionnaire" the representators of the third group had the highest level of excitability (7.50±1.60), anxiety (5.75±0.71), sensitivity (6.13±0.83), reverie (6.00±1.85), and diplomacy (6.63±1.92). They were marked by the highest indicators of tension (4.75±1.83). Due to the data received from the method "Self-Esteem Structures of Temper Questionnaire" the representators of the third group differed from others with the highest levels of introversion (14.13±6.22), emotional anxiety (11.50±4.44), and the lowest reaction pace (10.88±2.36). The representators of this group due to the method "Progressive Matrix" were diagnosed with the lowest level of IQ (95.13±11.70).

Everyone from group C with no exceptions were enlisted personnel with experience of service from 1 to 2 years, unmarried, a quarter of them had experience of participation in combat operations.

Such results gave the possibility to conclude that due to certain constitutional peculiarities (low neuropsychological resilience, emotional anxiety, and decreased intellectual abilities) these servicemen had difficulties with adaptation in new military surrounding and tried to decrease the emerged anxiety with typical for them way which was alcohol abuse.

DISCUSSION

The results which were received in this research proved one more time that ARIs were mostly committed by servicemen with lower military rank. The conclusion was considered to be typical, and it pointed out that servicemen who committed ARIs were characterized by the decreased quality of interaction with the surrounding substantive and social world (were less motivated, less active and less capable to rapid mobilization). They were characterized by lower level of extraversion, sociability, conformity, and practicality; moreover, they had lower indicators of intellectual abilities and awareness.

Combat operations in Eastern Ukraine has been already carrying out for 8 years already [33], thus a half of servicemen (50.32%) who took part in the research had the status of participants in hostilities. This fact could not be the indication that participation in combat operations increased the quantity of those who committed ARIs.

The research proved that the group of servicemen who committed ARIs was homogeneous and due to the specificity of adaptation it could be divided into three more groups. The most interesting fact was that a significant criterium of segmenting was the sincerity of answering the questions by servicemen. Thus, the biggest group of servicemen who committed ARIs in comparison with the control group was characterized by low level of sincerity of answers. They wanted to demonstrate their socially approved image. The same tendency was revealed in the process of analyzing the cadets from Higher Educational Military Institutions who were known to buy forbidden substances [34]. However, among the servicemen who committed ARIs the eagerness to demonstrate socially approved image was far more spread (there were 67.74% from the general group of analyzed servicemen who committed ARIs and 42.11% from the general group of analyzed military cadets who were known to use forbidden substances).

The determination of groups in this research was quite important to figure out the reasons of ARIs and their spreading. The representators of group A, in particular, understood the importance of rules and norms of behavioral regulation; however, they experienced the crisis connected with realization of their own inconsistency to norms and values which regulated the activity of servicemen. Servicemen from subgroup A1 had such crisis due to the process of overthinking of values, while servicemen from subgroup A2 were characterized not only by inconsistency to norms, but also by low possibility to control their reactions and believe to existing rules. The vast majority of subgroup A2 were enlisted personnel of the 1st year of service. Specifically, the problem of the secondary socialization was the reason of ARIs' commitment by those servicemen. Group A was not so widespread as it was generally considered. Thus, about 12% of the group of servicemen who committed ARIs had the problems of the secondary socialization (problems of accepting the norms of new social group) and the crisis of values.

Among the representators of group B there was distinguished subgroup B1. The representators of subgroup were sincere, active, and intellectually developed, they could rapidly mobilize their strength, but they were not ambitious and were unmotivated while executing their duties of low enforcement. Received results concerning this group proved the conclusions made by Kintzle at alia [24] that unemployment was the reason of stress and alcohol abuse. The case was not in unemployment but in absence of favourite work which could provide them with self-realization; namely that turned to be the reason of ARIs' commitment. Moreover, the research conducted by Hoopsick, Homish, Vest, & Homish [35] pointed out that servicemen of the US Army and the US National Guard who did not participate in hostilities had negative concerns on the fact of being unrealized that became the predictor of addictive behaviour.

The representators of subgroup B2 had tendency to negative concerns which disorganized their activity. However, taking into account the high level of their insincerity it was possible to conclude that they tended to use references to their miseries as excuses of their impertinence and alcohol abuse. These servicemen demonstrated victim-like behaviour and according to Kim et alia [28] that was one of the reasons of alcohol abuse in junior military personnel. However, another research by Hoopsick, Homish, Vest, & Homish G [36] distinguished that the negative social relations such as problems of perceptions and social victimization were connected with higher chances of forbidden substances abuse and non-medical use of prescribed medications among the servicemen of the US National Guard. However, those problems did not lead to the increase of alcohol abuse.

Subgroups B3 and B4 were the biggest ones and they both wanted to increase their status. Thus, the servicemen of subgroup B3 while abusing alcohol tried to add themselves the traits of proficiency and to develop their image of experienced servicemen. The servicemen of subgroup B4 wanted to become important individuals. Both subgroups abused alcohol and that gave them the possibility not only to feel themselves more confident and independent but also it was a significant component for their image of successful individuals. According to the research by Barry et alia [7] and Shirvani et alia [8] such reasons of alcohol abuse explained why among those who wanted to enter the military service there were more school-leavers and youth who abused alcohol than those who did not have such habit.

Connection between alcohol abuse and problems of identification was examined in the work by Lostutter, Neighbors, Simpson, & Larimer [37]. The researchers distinguished that identifying themselves as a veteran and/ or a student at the college could influence the connection between the status of veteran and alcohol as well as psychological symptoms. They figured out that when veterans who were studying in college started identifying themselves as typical students at the college it decreased the symptoms of PTSD.

The features of group C of servicemen who committed ARIs turned out to be significantly close to those which were distinguished in our previous works devoted to the analysis of constitutionally weak subtype among the servicemen who committed suicide [38]. The comparison of groups such as "the control group" (1), "constitutionally weak who committed suicide" (2), "constitutionally weak individuals who committed alcohol-related incidents" (3) demonstrated that the last group had worse or even the worst nature to confront all the life failures as well as "constitutionally weak individuals who committed suicide" (2). Furthermore, earlier Prykhodko I, Matsehora, Kolesnichenko, Pasichnik, Kuruch, Yurieva, Kravchenko, Radko, & Prikhodko D [39] determined that constitutionally weak individuals did not tend to commit suicide while being drunk because they reacted on alcohol abuse as on absolute relaxation. This information gave the possibility to regard alcohol as if it was a coping which protected from suicide commitment.

Received results from group C proved the determined by Herberman Mash et alia [5] thesis that understanding of the reasons of alcohol abuse helped to distinguish the subgroups of servicemen who either tended to risky suicidal behaviour or were stable concerning suicide.

All the servicemen who committed ARIs were characterized by the decrease of the quality of interaction with the surrounding substantive and social world; however, the reasons of their alcohol abuse significantly differed. As a criterium for segmenting in the research there were used indicators of (dis)adaptivity which transferred the review of the topic concerning alcohol abuse to the plane of unproductive copings and relevant description of the groups such as "inconsistency to the norms" (group A), "desire to demonstrate socially approved image" (group B), "protection from suicide commitment" (group C).

Among the servicemen who committed ARIs there were distinguished three groups such as A, B, and C which differed with their peculiarities of (dis)adaptation. That was valuable to organize preventive works, events dedicated to the improvement of socialization by recruits, adequate formation of servicemen image as well as their identification in accordance with it, and events dedicated to the prevention of suicidal behaviour.

The results of this research will be used to specify the norms in accordance with psychodiagnostic methods due to which the psychological and professional selection to the military service are carried out.

Typology and structure of servicemen motivation

Yanina Matsegora[1], Oleksandr Kolesnichenko[2], Ihor Prykhodko[2], Svitlana Izbash[4], Vitalii Panok[4], Marushchenko Kateryna[5], Rumiantsev Yurii[6], Natalia Miloradova[7], Marat Kuznietsov[8], Ihor Sohan[8]

Abstract: *The results of the conducted research gave the possibility to distinguish the structure of the motivation which was suitable for the distinguished types of motivation of servicemen of the National Guard of Ukraine with different levels of effectiveness of their professional activity including motivation based on public service, stagnation, prosaically, romantic, deficient, and dependent. 2435 male servicemen participated in the research. They equally represented all the operational and territorial reunifications and military units of the National Guard of Ukraine. Every unit equally presented the officers, servicemen under the contract including the participants in hostilities as well as those who did not have such experience. The research was conducted with the help of the methods which were standardized by the Ukrainian language: "Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs", "Methods of Studying the Motivational Profile of Personality", and "Motivation Sources Inventory – MSI". The conducted research posed the possibility to describe not only the determined types of professional motivation of servicemen, but also specific phenomena such as self-motivation of the representatives of a type which was run by public service motivation; "rest on the laurels" for the type of stagnation; problems related to choice-making for the prosocial type for whom profession, family, and friends had equal meaning; the tendency for manipulation to gain access to desirable aspects of professional activity of the type which struggled for adventures; lack of sincere interest in the military profession for the deficient type which could change it for more prospective having the same requests for the candidates; attitude to the profession as if it was a means of satisfaction of the needs of their emotional life for the dependent type.*

Keywords: *motive, motivational sphere, servicemen, the effectiveness of the professional activity*

INTRODUCTION

With the beginning of combat operations in Eastern Ukraine, it turned out to be obvious that the estimation system of motivation of servicemen of NGU did not satisfy all the requirements related to the profession [1]. The number of those who wanted to sign a contract or to prolong it had significantly decreased. However, there increased staff turnover, the number of violations of discipline related to alcohol and drug abuse [2], spontaneous unit leaving, ignoring and defying orders, and other issues which were closely connected with discrepancy of servicemen motivation to profession requirements. It turned out to be urgent to determine the adequate motivation of professional activity for servicemen of NGU and to select and develop new psychodiagnostic methods to estimate it.

Having analyzed the world experience of studying the motivation of servicemen and law enforcement there was a need to point out that these days it was implemented in the frames of the theory of public service motivation (PSM), self-determination theory (SDT), and terror management theory

(TMT) [3]. They were used to explain the selection of serviceman profession, the effectiveness (productivity, success) of professional activity, achievement of aims related to the activity, satisfaction with professional activity, professional burnout, exhaustion, and staff turnover.

Israeli researchers Taubman-Ben-Ari and Findler [3] studied the conscripts by the terror management theory (TMT). It was distinguished that the main psychological conflict occurred due to the existence of self-preservation instinct through understandability that death was irreversible and unpredictable. They concluded that the significance of death rate related to higher level of motivation directed to public service and higher expectations of physical difficulties in the army.

According to Griffith and Perry [4] the motives of military service enlistment before as well as after the operation "Desert Storm" was explained by the following factors: "desire to perform military service", "personal development", "salary (benefits)", and "career development". However, after the operation "Desert Storm" there significantly decreased the number of recruits entering military colleges due to three first factors from the list.

Like-Jensen and Glad [5] studied the motives of entering the missions of preservation and implementation of peace. They determined three types of servicemen motives among them there were: challenge, personal well-being, and loyalty. Challenge was the motivation directed to the profession. Personal well-being was a desire to get adventures (romantic motivation). Loyalty was the institutional motivation. Motives before as well as after the participation in hostilities significantly differed in dependence on the type of mission.

Siryi [6] pointed out that among the servicemen who served under the contract in the Armed Forces of Ukraine there were spread three types of motivation "motivation of activity" (36.6%), "motivation of pragmatics" (58.6%), and "motivation of reward" (4.8%).

Chambel, Castanheira, Oliveira-Cruz, and Lopes [7] having compared the studies carried out by Portuguese servicemen distinguished that motivation directed to autonomous work was positively connected with the involvement into the work as well as negatively connected with burnout. Controlled motivation, in turn, demonstrated an opposite picture. Moreover, autonomous motivation was a mechanism that explained the interrelation between contextual factors and well-being at workplaces.

Gillet, Becker, Lafrenière, Huart, and Fouquereau [8] distinguished that servicemen with high indicators of autonomous motivation showed the highest level of well-being including the support from the side of leaders, positive worries, communication, and a high level of organizational support.

Based on the carried out studies Breaugh, Ritz, and Alfes [9] pointed out the interconnection between the theory of public service motivation (RSM) and the theory of self-determination (STD). Having learned their relations with work satisfaction gave the possibility to figure out that the motivation of self-determination was significantly bound with the satisfaction at work-position. However, the co-workers with a high level of PSM had more stable indicators of work satisfaction in comparison with their colloquies who had a low level of PSM.

Schott, Neumann, Baertschi, and Ritz [10] conducted the comparison of prosocial motivation as well as public service motivation and studied the peculiarities of Swiss police officers. These researchers determined that despite PSM and prosocial motivation Swiss police officers were motivated with various tasks and excitement (for example, car chases). In daily routine, they were motivated by complicated tasks, by the way, they were estimated by the public and their colleagues.

The research conducted by Holton, Smith, Lindsay, and Burton [11] distinguished that a desire of cadets of the US Air Force Academy to voluntarily resign was negatively connected with work satisfaction, emotional commitment, work engagement, and individual compliance with professional requirements. The researchers figured out that the strongest predictor of staff turnover was individual compliance with the profession.

Meyer, Kam, Goldenberg, and Bremner [12] determined that Canadian servicemen with high indicators of affectivity and normative commitment of organization reported about the most favorable conditions at work, desire to continue their service and well-being. Servicemen who were focused on the consequences of their actions (understandability of the "price" of the resign consequences) and informed about less favorable consequences were more active in their search for work and had the highest level of anxiety and depression.

Lakhani and Fugita [13] studied the problem of resignment among the US Army and the National Guard reservists after the "Desert Storm" from the side of income and patriotism. They determined that the decrease of those who resigned from service could happen due to the increase of salary for reservists or due to the encouragement of wife/husband for a more positive attitude to reservists. However, the results of this research turned out to be weak support of the income theory but gave significant support for the patriotism theory.

The presented analysis showed that there was a need to consider heterogeneous motives of professional activity of servicemen as well as of law enforcement officials. Moreover, the search manner of this research proved the necessity to decrease the number of analyzed variables to increase the accuracy of the perception of the received results. By the highlighted information, the empirical data received in the research proceeded to factorial analysis.

METHOD

Participants and Procedure

The research was conducted throughout the 2019-2021 years. 2435 servicemen of the National Guard of Ukraine participated in the research. Those servicemen equally represented all the operational and territorial reunifications as well as military units of the National Guard of Ukraine. Every unit equally presented the officers – 29.84% (from the second lieutenants to colonels), servicemen who served under the contract – 70.16% (from soldiers to senior warrant officers), participants in hostilities, and those who did not have such experience. The age of all the participants was from 20 to 55. All procedures carried out in the study conformed to the ethical standards of the 1964 Helsinki Declaration and its later amendments. All participants gave consent for their data to be used in this research.

Instruments and Measures

To determine the structure of motivation which was typical for the distinguished type of NGU servicemen motivation with various levels of effectiveness of professional activity there were used the methods standardized by the Ukrainian selection:

1. “Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs” by Moskalienko [14]. This questionnaire was developed by the Ukrainian researcher for professional psychological selection for future policemen education; it gave the possibility to evaluate “Motives Related to Objective Socially Posed Tasks and Content of Profession”, “Motives Related to Personal and Professional Development”, “Independent Profession Selection”, “Dependent Profession Selection”, “Motives Related to External Prestigious Professions and Financial Welfare”, “Motives Related to Romanticization of Profession”, “Motives Related to Eagerness of Compensation of Temper Flaws”, “Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)”. The instruction of this method proposed to answer the question concerning the reason for choosing this profession where the respondents using a scale made of 5 points could estimate 40 statements that described the profession of law enforcement.

2. “Methods of Studying the Motivational Profile of Personality” by Ritchie and Martin [15]. The use of this method gave the possibility to determine the urgent motivation of professional activity. It had the following scales: “Need of High Salary and Financial Benefits”, “Need of High Working Conditions and Comfortable Surrounding”, “Need of Accurate Structurization of Work and Feedback”, “Need of Social Relations”, “Need of Forming and Supporting Long-Term Stable Relations”, “Need of Obtaining the Recognition by Other People”, “Need of Posing Brave and Tough Goals and of Achieving Them”, “Need of Interesting and Socially Beneficial Work”, “Need of Self-Improvement and Development as Personality”, “Need of Being Creative, Thoughtful, and Open for further Ideas Employee”, “Need of Diversity, Breaks, and Stimulations, Eagerness to Avoid Everyday Routine”, “Need of Manipulation and Power, Eagerness to Control the Other People”. This questionnaire included 33 questions with 4 variants of answers where the respondents had to place 11 points by the importance of the answers.

3. “Motivation Sources Inventory – MSI” by Barbuto and Scholl [16]. The use of this method gave the possibility to determine: “Internal Processes” (a desire to get satisfaction and pleasure from the process of activity), “Instrumental Motivation” (desire to valuable external benefits such as benefits, etc.), “External conception – I” (desire to except and support personal traits, competencies, and values from the side of other individuals or referential group), and “Internal competence – I” (desire to achieve aims and relevant internalized values). Respondents were proposed to answer 30 questions related to profession using a 7-point scale (from complete “no” to complete “yes”).

Data Analysis

To determine the structure of motivation which was typical for every distinguished type there were used the extraction method: principal component analysis and rotation method: varimax with Kaiser normalization. As variables, there were represented the indicators by scales of three psychodiagnostic methods. Mathematical data was processed through SPSS 17.0.

RESULTS

According to previously carried out research there were distinguished the following types of NGU servicemen motivation with different levels of effectiveness of their professional activity: motivated by public service, stagnated, prosocial, romantic, deficient, and dependent [17].

The first type of motivation of NGU servicemen (about 35% from general selection) was marked as one which was run by public service motivation. Servicemen of this type chose the military profession due to its content, goals, and desire to develop. They had expressed orientation directed to socially beneficial work as well as professional development. The motives which described the conditions, working hours, and social interaction were significantly lower and subcontract. Those servicemen had high indicators of a need for high financial benefits and recognition which demonstrated the importance of the high social status of the chosen profession. It was typical for the representation of this group to have significant time prospects, distinct internal locus control, and developed strong-willed qualities.

Used factors of the analysis showed that resistance and mentioned peculiarities of professional motivation ensured specific structure for the representation of this type. The motivational structure of this type is represented in Table 1.

Table 1: The structure of motivation of NGU servicemen who were guided by PSM

Variables	Factors					
	1	2	3	4	5	6
Motives Related to Objective Socially Posed Tasks and Content of Profession	0.73	-0.01	0.13	-0.21	-0.13	-0.30
Motives Related to Personal and Professional Development	0.81	0.12	-0.01	-0.13	-0.05	0.14
Independent Profession Selection	0.73	-0.01	-0.29	0.04	-0.04	-0.13
Motives Related to External Prestigious Professions and Financial Welfare	0.75	0.05	-0.07	0.33	0.08	0.12
Motives Related to Eagerness of Compensation of Temper Flaws	0.82	0.03	0.10	-0.05	-0.14	0.06
Need of High Working Conditions and Comfortable Surrounding	-0.05	0.07	0.07	0.91	-0.15	-0.11
Need of Accurate Structurization of Work and Feedback	0.07	0.87	-0.05	-0.13	-0.16	-0.14
Need of Obtaining the Recognition by Other People	-0.14	-0.01	0.02	-0.15	0.93	-0.04
Need of Diversity, Breaks, and Stimulations, Eagerness to Avoid Everyday Routine	-0.06	-0.85	-0.03	-0.25	-0.16	-0.01
Need of Self-Improvement and Development as Personality	0.02	-0.12	0.07	-0.10	-0.05	0.93
Internal Processes	0.03	-0.05	0.83	-0.10	-0.20	0.14
Instrumental Motivation	-0.09	0.04	0.81	0.20	0.28	-0.08
Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.						
a. Rotation converged in 6 iterations.						

This factor structure explained 77.59% of total dispersive features. The first and the most significant factor (24.90%) was distinguished with the help of the following variables: “Motives Related to Eagerness of Compensation of Temper Flaws” (0.82), “Motives Related to Personal and Professional Development” (0.81), “Motives Related to External Prestigious Professions and Financial Welfare” (0.75), and “Motives Related to Objective Socially Posed Tasks and to Content of Profession” (0.73). This factor was marked as a desire to gain professional dignity – the desire for personal, professional, and social development turned to the professional requirements.

The second and the third factors had almost the same value in this structure (12.64% and 12.32%) and were part of the mechanism of self-motivation. Therefore, the second factor demonstrated a desire to produce and practice the professional algorithm of actions: “Need of Accurate Structurization of Work and Feedback” (0.87) and “Need of Diversity, Breaks, and Stimulations, Eagerness to Avoid Everyday Routine” (-0.85). The third factor showed the process of enjoying professional activity (process as well as result). It was described with the help of the variables such as “Internal Processes” (0.83) and “Instrumental Motivation” (0.81).

Such a combination of the second and the third factors gave the possibility to highly effective servicemen to support their high level of professional activity, accuracy, and intensity of the professional activity.

The three last factors also had almost identical values (9.61%, 9.15%, and 8.96%, accordingly) and they described the peculiarities of needs’ satisfaction. Thus, the content of the fourth factor was connected with the conviction that the financial benefits received due to hard work related to the objective content of the profession. The fourth factor was characterized with “Need of High Working Conditions and Comfortable Surrounding” (0.91). Having clarified that the content of this factor had positive correlations with the variable such as “Motives Related to External Prestigious Professions and Financial Welfare” (0.33) and negative correlations with the variable such as “Need of Diversity, Breaks, and Stimulations, Eagerness to Avoid Everyday Routine” (-0.25) and of “Motives Related to Objective Socially Posed Tasks and to Content of Profession” (-0.21). It was figured out that namely, the achievement of professional aims and the performance of professional duties were the source of financial well-being.

The content of the fifth factor was in the fact that favorite activity was the source of social approvement. The fifth factor was described with the help of the variable such as “Need of Obtaining the Recognition by Other People” (0.93). Its content was clarified with the direct connection with the variable “Instrumental Motivation” (0.28) and with the resource-based connection with the variable such as “Internal Processes” (-0.20).

The sixth factor correlated with the variable “Need of Self-Improvement and Development as Personality” (0.93). Negative connection correlated with the variable such as “Motives Related to Objective Socially Posed Tasks and Content of Profession” (-0.30). It was determined that namely the profession, its aims, and content were the resource of personal development for servicemen of this type. Thus, the reference point of the acquisition of professional dignity by the first type of NGU servicemen was the combination of a desire for professional, personal, and social development with a desire of meeting the requirement of the profession and running its aims. In this structure of the motivation, there was determined the mechanism of self-motivation and support of activity on a high level which was foreseen by the process of producing and practicing professional algorithm of actions as well as by the satisfaction of working processes and its results. Such a structure of motivation of servicemen provided them with a high level of effectiveness in their profession, with a desire to follow the rules, and with close affection to their profession. It provided them with the prevention from professional stagnation and gave them the possibility to support the accuracy and intensity of their professional activity.

Servicemen of the stagnated type (it compiled about 15% from a general selection of this research) also chose the military profession due to its content. They had significant achievements in professional activity, recognition of their success, but they did not want any professional development, challenges, and responsibility. They tried to distance themselves from their colleagues in service. The structure of motivation of this type is presented in Table 2.

Table 2: The structure of motivation of NGU Servicemen who experiences stagnation

Variables	Factors					
	1	2	3	4	5	6
Motives Related to Objective Socially Posed Tasks and Content of Profession	0.26	-0.01	0.03	0.79	0.01	-0.09
Dependent Profession Selection	-0.08	0.86	0.04	-0.07	-0.05	-0.02
Motives Related to Eagerness of Compensation of Temper Flaws	-0.15	0.18	-0.10	0.86	-0.03	0.16

Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.						
a. Rotation converged in 6 iterations.						

This factor structure included 77.12% of the total dispersion of the peculiarities.

The structure of servicemen motivation who experienced stagnation, the first and the most valuable factor (16.50%) demonstrated an expressed individualism in the process of achieving professionally important aims based on interiorized professional values. This factor was marked with the variables such as “Internal Conception – I” (0.81). “Internalization of the Aim” (0.81), and “Instrumental Motivation” (0.77). There was clarified the content of the variables of this type’s factor “Motives Related to Objective Socially Posed Tasks and Content of Profession” (0.26) and “Need of Accurate Structurization of Work and Feedback” (-0.24).

The content of the second factor (13.70%) was highlighted due to such variables as “Dependent Profession Selection” (0.86) and “Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)” (0.77). This factor was clarified with the help of the positive poles of the variables such as “Instrumental Motivation” (0.24) and “Need of Social Relations” (0.21) as well as negative poles of the variables such as “Internal Processes” (-0.34), “Need of Accurate Structurization of Work and Feedback” (-0.29), and “Internal Conception – I” (-0.28). This factor was described as a forced compromise. It was quite important for servicemen to gain financial benefits, but it did not provide them with any kind of satisfaction.

The next three factors had almost identical values (12.48%, 12.03%, and 11.85%, accordingly). These factors developed the mechanism to support positive self-relationship which preserved their achievements. The content of the third factor was expressing themselves as role model for other servicemen. The positive pole of the third factor was marked with the variable such as “Need of Social Relations” (0.87) and clarified positive poles with the variable such as “Internal competence – I” (0.20). The negative pole of the third factor was marked with the variable “Need of High Salary and Financial Benefits” (-0.88). Some clarifications were conducted with “Instrumental Motivation” (-0.17). Thus, it was very important for servicemen of the stagnated type to demonstrate their principles to the surrounding in opposition to their financial benefits.

The fourth factor was marked with the variables such as “Motives Related to Eagerness of Compensation of Temper Flaws” (0.86) and “Motives Related to Objective Socially Posed Tasks and to Content of Profession” (0.79). It was clarified the variable “Antisocial Motives” (0.29). Such a combination of the variables of the fourth factor described a desire of servicemen to gain importance at the expense of using all the possibilities given by the profession for their purpose.

The fifth factor had significantly marked poles which provided a positive description to the variables such as “Need of High Working Conditions and Comfortable Surrounding” (0.87) and the reversed was “Need of Obtaining the Recognition by Other People” (-0.85). This factor marked the refusal from professional ambitions of servicemen to the benefit of peaceful life till the end of their contract. In other words, they wanted to rest on laurels.

The sixth factor (10.57%) also had marked poles. The positive pole was “Internal Processes” (0.80). Its content was clarified with the variables such as “Instrumental Motivation” (0.23) and “Motives Related to Eagerness of Compensation of Temper Flaws” (0.16). The negative pole was marked with a variable such as “Need of Accurate Structurization of Work and Feedback” (-0.76). This factor was marked as being satisfied at the expense of demonstrating their honed professional skills.

Having summed up the results of servicemen who were included in the stagnated type there was a need to point out that they were characterized with marked individualism and perception of the service continuation as a forced compromise. The structure of their motivation had a formation due to which they supported high positive self-relationship, demonstrated their integrity and success at the expense of carrying out the improvement of professional skills, and used the position of “rest on laurels”.

Servicemen of the prosocial type (15%) even if they considered their military service to be temporal work which gave them the possibility to make living for their families, however, they made huge efforts to acquire military profession to realize its sense and content. They were responsible performers and did not require additional control from the side of their commanders. It was important for them to support friendly relations with colleagues in service and recognition of their combat achievements by society including financial benefits (benefits). The structure of motivation of this type is presented in Table 3.

This factor structure explained 77.75% of the total dispersion of the peculiarities. The factors had almost equal values.

Thus, the first factor which compiled 15.03% was marked with the variables such as “External Conception – I” (0.87), “Instrumental Motivation” (0.78), and “Internalization of the Aim” (0.73). It was marked as a desire to be accepted by military colleagues and to be helpful to them.

Table 3: The structure of motivation of NGU Servicemen of prosocial type

Variables	Factors					
	1	2	3	4	5	6
Motives Related to Objective Socially Posed Tasks and Content of Profession	0.12	-0.04	0.02	0.08	0.13	0.90
Dependent Profession Selection	0.01	0.11	0.89	0.06	0.07	0.03
Motives Related to Romanticization of Profession	0.22	0.08	0.74	0.22	0.05	0.33
Motives Related to Eagerness of Compensation of Temper Flaws	0.14	0.04	0.44	-0.19	0.08	0.74
Need of High Salary and Financial Benefits	0.07	0.72	0.30	0.06	-0.11	0.08
Need of Accurate Structurization of Work and Feedback	-0.14	0.85	-0.04	0.05	0.14	0.01
Need of Social Relations	0.11	-0.28	0.29	0.71	-0.30	-0.06
Need of Forming and Supporting Long-Term Stable Relations	-0.03	-0.77	-0.01	0.37	0.21	0.14
Need of Obtaining the Recognition by Other People	0.15	-0.21	-0.12	-0.13	0.87	0.08
Need of Diversity, Breaks, and Stimulations, Eagerness to Avoid Everyday Routine	0.16	-0.12	-0.32	0.02	-0.78	-0.14
Need of Interesting and Socially Beneficial Work	-0.18	-0.07	-0.02	-0.94	-0.01	-0.01
Instrumental Motivation	0.78	0.01	0.17	0.13	-0.11	0.15
External Conception – I	0.87	0.07	0.09	-0.02	-0.05	-0.01
Internalization of the Aim	0.73	-0.19	-0.08	0.21	0.20	0.14

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization.

a. Rotation converged in 6 iterations.

The positive pole of the second factor (14.62%) was marked with the variables such as “Need of Accurate Structurization of Work and Feedback” (0.85) and “Need of High Salary and Financial Benefits” (0.72). The reversed pole of a factor was marked with the variables such as “Need of Forming and Supporting Long-Term Stable Relations” (-0.77) and was clarified with the help of “Need of Obtaining the Recognition by Other People” (-0.21). The second factor testified that the representations of this group's military profession were temporal means of high income which they left their families for. Choosing this profession, the final step for servicemen was the possibility to acquire the profession and to earn with its help.

The content of the third factor (13.24%) was connected with the variables such as “Dependent Profession Selection” (0.89) and “Motives Related to Romanticization of Profession” (0.74). This factor clarified “Motives Related to Eagerness of Compensation of Temper Flaws” (0.44), “Need of High Salary and Financial Benefits” (0.30), and “Need of Diversity, Breaks, and Stimulations, Eagerness to Avoid Everyday Routine” (-0.30). Such combination gave the possibility to conclude that the choice of military profession was made under the influence of family, friends, and familiar people who described this profession which was connected with adventurous (romantic), hard, sometimes routine-like but, at the same time, highly paid.

The positive pole of the fourth factor (12.12%) corresponded with variables such as “Need of Social Relations” (0.71). The clarified variables were “Need of Forming and Supporting Long-Term Stable Relations” (0.37), “Motives Related to Romanticization of Profession” (0.22), and “Internalization of the Aim” (0.21). The reversed pole was marked with a variable such as “Need of Interesting and Socially Beneficial Work” (-0.94). In the majority of cases, servicemen of the prosocial type were motivated with the accurate realization of military fellowship and friendship; they wanted to find real friends and to have identical aims with them.

The fifth factor (11.53%) also had both distinguished poles. The positive features mostly correlated with the variable such as “Need of Obtaining the Recognition by Other People” (0.87). The clarified variable was “Internalization of the Aim” (0.20). The reversed pole was introduced in “Need of Diversity, Breaks, and Stimulations, Eagerness to Avoid Everyday Routine” (-0.78) and “Need of Social Relations” (-0.30). This factor was marked as a desire to get recognition of achievements gained with the help of hard work and tasks performance but not at the expense of friendly relations.

The sixth factor (11.21%) was correlated with the variables such as “Motives Related to Objective Socially Posed Tasks and Content of Profession” (0.90) and “Motives Related to Eagerness of Compensation of Temper Flaws” (0.74). The clarification of its content was done due to the variable

“Motives Related to Romanticization of Profession” (0.33). For servicemen of the prosocial type, the abstract content of professional activity “Serve and Protect” gained completely accurate meaning including such features as coping with their fears and flaws, presenting their desires, learning how to use the weapon, improving their physical strength, being good colleague, etc.

It was important for servicemen of this type to be the good breadwinner for their families, to be helpful in their professional activity, and to be reliable for their colleagues in service. They seemed to be more relatives-centered than socially centered.

Servicemen who were focused on the satisfaction of their personal needs (6%) were the only ones from the whole range of distinguished types who chose the profession due to mercenary interests and not due to the objective content of the profession. These servicemen wanted to beneficially exchange their professional skills for their financial well-being. They used social relations because they got satisfaction from communication. They did not want to be responsible, did not want to realize their volitional qualities. These servicemen demonstrated indifference to the problems of their colleagues in service. They were not active because it did not bring them any additional income. Almost 75% of servicemen of this type had the status of the participants in hostilities. These servicemen admired the adventures and neglected the content of the military profession. Their actions were constantly controlled by their commanders. This type was marked as one motivated by a desire for adventures. The structure of motivation of this type is presented in Table 4.

Table 4: The structure of motivation of NGU Servicemen who were motivated with their desire to have adventures

Variables	Factors					
	1	2	3	4	5	6
Motives Related to Objective Socially Posed Tasks and Content of Profession	0.05	0.15	-0.01	-0.12	0.87	-0.09
Motives Related to Personal and Professional Development	0.82	-0.17	-0.15	0.07	-0.04	0.07
Dependent Profession Selection	0.82	-0.22	0.26	0.01	-0.15	-0.24
Motives Related to Romanticization of Profession	0.73	-0.04	0.28	0.27	0.34	0.01
Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)	0.79	0.26	-0.10	-0.08	0.10	0.39
Need of High Salary and Financial Benefits	-0.07	-0.36	-0.72	0.27	-0.01	-0.35
Need of Accurate Structurization of Work and Feedback	0.06	-0.02	0.09	-0.08	-0.08	0.94
Need of Social Relations	-0.17	0.81	0.02	-0.05	0.16	0.08
Need of Forming and Supporting Long-Term Stable Relations	0.05	-0.03	0.93	-0.02	0.02	-0.04
Need of Posing Brave and Tough Goals and of Achieving Them	0.08	0.06	-0.12	0.70	-0.46	0.01
Need of Being Creative, Thoughtful, and Open for further Ideas Employee	0.07	-0.70	0.20	0.23	0.38	0.27
Need of Self-Improvement and Development as Personality	-0.08	0.16	0.08	-0.89	-0.09	0.11
Need of Interesting and Socially Beneficial Work	-0.06	0.75	0.31	-0.14	0.02	0.04
Internal Conception – I	0.12	0.71	-0.03	0.29	0.45	0.07

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization.

a. Rotation converged in 9 iterations.

The presented factor structure explained 80.65% of the total dispersion of the peculiarities.

The first factor (18.45%) characterizes military personnel as prone to gambling to achieve their interests due to the awareness of their lack of existing skills and personal qualities. This factor included such variables as "Motives related to personal and professional development" (0.82), "Dependent choice of a profession" (0.82), "Asocial motives (attitude towards the profession as a way to satisfy one's own asocial needs)", (0.79) and "Motives associated with the romanticization of the profession" (0.73).

The second factor (18.24%) described the search for the surrounding which could make the lives of servicemen more interesting and eventful. The positive pole of this factor was connected with the variables such as “Need of Social Relations” (0.81), “Need of Interesting and Socially Beneficial

Work" (0.75), and "Internal Conception – I" (0.71). Somewhat specific meaning to this factor was given with the variable such as "Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)" (0.26). The reversed pole was marked with a variable such as "Need of Being Creative, Thoughtful, and Open for further Ideas Employee" (-0.70). There were clarified the variables of the reserved pole such as "Need of High Salary and Financial Benefits" (-0.36) and "Dependent Profession Selection" (-0.22). Thus, these servicemen did not tend to perform something new, creative. They searched for interesting surroundings that made their lives eventful.

The third and the fourth factors were similar in their values. The third factor (12.24%) characterized a desire of servicemen to use financial resources and gained stable social relations. That could diversify their professional activity and made it more romantic. The fourth factor (11.58%) described servicemen which wanted to get superiority over other people, to self-realize at the expense of desperate actions as opposed to a desire of self-development as well as of development of personal individuality. Servicemen of this type with the help of all possible means wanted the profession to correlate with their "romantic" expectation; however, they did not even try to comply with all the real requirements of the military profession.

Thus, the positive pole of the third factor (12.24%) was connected with variables such as "Need of Forming and Supporting Long-Term Stable Relations" (0.93). It was clarified with the help of the variables such as "Need of Interesting and Socially Beneficial Work" (0.31), "Motives Related to Romanticization of Profession" (0.28), and "Dependent Profession Selection" (0.26). The negative pole was described with variables such as "Need of High Salary and Financial Benefits" (-0.72). The content of this factor indicated that servicemen wanted some adventures and refused financial benefits.

The positive pole of the fourth factor was connected with the variable such as "Need of Posing Brave and Tough Goals and of Achieving Them" (0.70). The content of this pole was clarified with the help of the variables such as "Internal Conception – I" (0.29), "Motives Related to Romanticization of Profession" (0.27), "Need of High Salary and Financial Benefits" (0.27), and "Need of Being Creative, Thoughtful, and Open for further Ideas Employee" (0.23). The reversed pole was determined with a variable such as "Need of Self-Improvement and Development as Personality" (-0.89). According to the content of this factor servicemen of this type tended to desperate acts to build self-esteem and to experience the emotions of priority over other people.

The fifth factor (10.66%) described servicemen who used a lot of creativity to avoid dangerous tasks to perform professional duties. It was correlated with variables such as "Motives Related to Objective Socially Posed Tasks and Content of Profession" (0.87). Its content was clarified with the variables such as "Internal Conception – I" (0.45), "Need of Being Creative, Thoughtful, and Open for further Ideas Employee" (0.38), and "Motives Related to Romanticization of Profession" (0.34). The reversed pole was marked with variables such as "Need of Posing Brave and Tough Goals and of Achieving Them" (-0.46). Servicemen of this type put huge efforts to shift the accents of their profession from dangerous features to adventurous ones. They mostly used the tasks which were attractive for them, and which met their romantic impressions related to the military profession.

The sixth factor (9.47%) was connected with the variable such as "Need of Accurate Structurization of Work and Feedback" (0.94). Its content was clarified with the variables such as "Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)" (0.39), "Need of Being Creative, Thoughtful, and Open for further Ideas Employee" (0.27), "Need of High Salary and Financial Benefits" (-0.35), and "Dependent Profession Selection" (-0.24). This factor described the servicemen who wanted to get work with definite support (personal interests) even if there was a need to use financial benefits.

Servicemen of the deficient type (25%) chose the military profession because of its content and wanted to change their lives. It was important for them to have a profession with a high salary and social status. Servicemen who wanted to work put huge efforts; however, their motivation turned out to be "blocked" with unsatisfied deficient needs. It negatively reflected on their effectiveness. The structure of motivation of this type is presented in Table 5.

This factor structure explained 77.73% of total dispersal peculiarities.

The most valuable first factor (21.40%) was marked with the variables such as "Motives Related to Eagerness of Compensation of Temper Flaws" (0.90), "Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)" (0.82), "Motives Related to Personal and Professional Development" (0.81), and "Motives Related to External Prestigious Professions and Financial Welfare" (0.76). It was marked as a desire to change themselves as well as to change their lives for the better, to go beyond their old way of living at the expense of their chosen military profession.

Table 5: The structure of motivation of NGU Servicemen of deficient type

Variables	Factors					
	1	2	3	4	5	6
Motives Related to Personal and Professional Development	0.81	-0.02	0.17	0.08	-0.27	0.09
Motives Related to External Prestigious Professions and Financial Welfare	0.76	0.09	0.06	-0.33	0.02	-0.04
Motives Related to Eagerness of Compensation of Temper Flaws	0.90	0.04	0.03	-0.01	0.12	-0.04
Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)	0.82	0.01	-0.11	-0.02	0.07	0.08
Need of High Working Conditions and Comfortable Surrounding	-0.12	-0.05	-0.01	0.92	0.06	0.03
Need of Social Relations	-0.02	0.03	0.84	-0.23	0.12	-0.13
Need of Forming and Supporting Long-Term Stable Relations	0.10	0.06	0.82	0.21	-0.14	-0.05
Need of Obtaining the Recognition by Other People	0.04	-0.08	-0.01	0.06	0.95	0.03
Need of Interesting and Socially Beneficial Work	0.07	-0.10	-0.15	0.03	0.03	0.96
Internal Processes	-0.11	0.78	-0.19	-0.18	-0.01	0.22
Instrumental Motivation	-0.05	0.75	0.23	0.23	0.11	-0.15
Internal Conception – I	0.20	0.79	0.09	0.06	-0.28	-0.09
Internalization of the Aim	0.07	0.78	0.02	-0.15	0.01	-0.13
Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.						
a. Rotation converged in 5 iterations.						

The second factor (18.76%) was marked with the variables such as “Internal Conception – I” (0.79), “Internal Processes” (0.78), “Internalization of the Aim” (0.78), and “Instrumental Motivation” (0.75). This factor was described as a desire to experience the feeling of their value.

The content of the third factor (11.81%) was distinguished with the variables such as “Need of Social Relations” (0.84) and “Need of Forming and Supporting Long-Term Stable Relations” (0.82). The content of this factor was clarified with the variables such as “Instrumental Motivation” (0.23), “Motives Related to Personal and Professional Development” (0.17), and “Internal Processes” (-0.19). This factor described servicemen who wanted to get new social surroundings, new social surroundings, a new social status which could change them as well as their financial situation due to their efforts.

The fourth factor (8.97%) correlated with “Need of High Working Conditions and Comfortable Surrounding” (0.92). Its content was clarified with the positive connections with the variables such as “Instrumental Motivation” (0.23) and “Need of Forming and Supporting Long-Term Stable Relations” (0.21). The reversed pole was marked with the variables such as “Motives Related to External Prestigious Professions and Financial Welfare” (-0.33) and “Need of Social Relations” (-0.23). Accordingly, the fourth factor was interpreted as an expressed need of servicemen to get welfare (good conditions and surrounding, competitive salary) without paying attention to the number of effort they put in.

The fifth factor (8.71%) correlated with the variable such as “Need of Obtaining the Recognition by Other People” (0.95). Its reversed pole gave the possibility to mark the connections with the variables such as “Internal Conception – I” (-0.28) and “Motives Related to Personal and Professional Development” (-0.27). Thus, this factor was marked as “Need of Obtaining the Recognition by Other People” which servicemen wanted to satisfy at the expense of personal development and professional improvement for what they could change their old persuasions and refuse from their old lives.

The sixth factor (8.08%) correlated with the variable such as “Need of Interesting and Socially Beneficial Work” (0.96). The content of this factor was clarified with the variables such as “Internal Processes” (0.22), “Instrumental Motivation” (-0.15), “Internalization of the Aim” (0.13), and “Need of Social Relations” (-0.13). This factor was marked as a desire for interesting and useful actions achieved through professional socialization.

Thus, servicemen of the deficient type had a marked desire to change themselves and their lives for the better, to go beyond the limits of the previous way of living, to experience the feeling of their value, and to get a new status. Their motivation was weakly connected with the direct content of the military profession despite a desire to work putting huge efforts and changing everything. Profession for them was a kind of means, not an individual value. Thus, the military profession could be substituted with any other which was more prospective having identical requirements for their candidates.

Servicemen of the dependent type (about 4% from a general selection of the research) were affective, weak-willed, dependent on other people, as well they expressed a desire for definite emotional life and had a low level of internality. According to the self-determination theory (SDT), there was traditionally used term "autonomous and controlled motivation". However, that type except "autonomous and controlled motivation" had some traits suitable for addictive behavior. The structure of motivation of this type is presented in Table 6.

Table 6: The structure of motivation of NGU Servicemen of dependent type

Variables	Factors					
	1	2	3	4	5	6
Motives Related to Personal and Professional Development	0.94	0.02	-0.11	0.12	0.05	0.08
Dependent Profession Selection	0.90	0.08	-0.15	0.31	-0.18	0.03
Motives Related to External Prestigious Professions and Financial Welfare	0.88	0.26	-0.30	-0.05	0.11	-0.01
Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)	0.86	0.29	0.16	-0.02	0.07	-0.24
Need of High Salary and Financial Benefits	0.24	0.10	0.10	0.93	-0.01	-0.09
Need of High Working Conditions and Comfortable Surrounding	0.04	-0.01	0.02	-0.03	0.96	0.14
Need of Accurate Structurization of Work and Feedback	-0.04	-0.01	-0.04	-0.10	0.15	0.98
Need of Obtaining the Recognition by Other People	0.18	-0.14	-0.87	-0.24	-0.28	-0.14
Need of Interesting and Socially Beneficial Work	-0.11	0.05	0.93	-0.10	-0.17	-0.17
Internal Processes	0.23	0.71	0.28	-0.46	0.24	0.20
External Conception – I	0.37	0.74	0.07	0.25	0.12	-0.06
Internal Conception – I	0.36	0.80	-0.04	0.09	-0.26	-0.14
Internalization of the Aim	-0.09	0.93	0.06	-0.01	-0.01	0.04
Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.						
a. Rotation converged in 6 iterations.						

This factor structure described 92.32% of total dispersal peculiarities.

The first two factors (28.01% and 21.16% accordingly) described the dependency on antisocial needs. The first factor pressed to the process of profession selection and the second factor was marked with specifically realized aims of professional activity.

The content of the first factor (28.01%) was marked with the variables such as "Motives Related to Personal and Professional Development" (0.94), "Dependent Profession Selection" (0.90), "Motives Related to External Prestigious Professions and Financial Welfare" (0.88), and "Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)" (0.86). This factor was marked as a forced selection made under pressure from their own needs including even antisocial personal ones (development, self-affirmation) and financial benefits.

The second factor (21.16%) was described through such variables as "Internalization of the Aim" (0.93), "Internal Conception – I" (0.80), "External Conception – I" (0.74), and "Internal Processes" (0.71). The content of this factor had the almost complete coincidence of the concept internalization of the aim with the situation when the achievement of the aim of valuable features of others was understood as self-realization and satisfaction of their activity. The content of this factor was clarified with the variables such as "Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)" (0.29) and "Motives Related to External Prestigious Professions and Financial Welfare" (0.26).

The third factor (14.45%) described a desire of servicemen to fill their personal life with a positive experience at the expense of their being a part of the interesting surroundings. Thus, usually dependent personalities had difficulties with the process of finding satisfaction inside themselves. To experience positive emotions, they needed external stimulation. The positive pole of the third factor was determined with “Need of Interesting and Socially Beneficial Work” (0.93). Definite clarifications were made with the variable such as “Internal Processes” (0.28). The reversed pole was marked with variables such as “Need of Obtaining the Recognition by Other People” (0.87). The clarification was made with the variable such as “Motives Related to External Prestigious Professions and Financial Welfare” (-0.30).

The last three factors had almost identical values – 10.27%, 9.49%, and 8.93% accordingly. The fourth factor described the specific attitude to the process of professional activity. This factor did not bring any satisfaction. Servicemen had to perform professional activities to get financial benefits (which was their main aim). This factor was formed with variables such as “Need of High Salary and Financial Benefits” (0.93). The content was clarified with a variable such as “Dependent Profession Selection” (0.31). The reversed pole was marked with a variable such as “Internal Processes” (-0.46).

The fifth factor was marked with a variables such as “Need of High Working Conditions and Comfortable Surrounding” (0.96). It was clarified with variables such as “Internal Processes” (0.24). The reversed pole was weakly marked with “Need of Obtaining the Recognition by Other People” (-0.28) and “Internal Conception – I” (-0.26). This factor was described as a desire to get comfort and hedonism.

The sixth factor (8.93%) was developed with variables such as “Need of Accurate Structurization of Work and Feedback” (0.98). The content of this factor was clarified with the variables such as “Internal Processes” (0.20) and “Antisocial Motives (attitude to the profession was as if it was a way to satisfy own antisocial needs)” (-0.24). This factor was described as a desire to avoid problems related to their activity, desire to obtain easy work.

Thus, the results of the conducted research gave the possibility to determine a range of peculiarities of the structure of motivation of servicemen of dependent type. Firstly, it provided the relations of dependency where personal development and well-being depended on the realization of their antisocial needs. Secondly, their activity was directed to the fulfillment of their interesting internal emotional life at the expense of their belonging to the interesting surroundings. Thirdly, their motivation was directed to the organization of the professional activity which did not disturb their internal emotional life, did not bring any troubles, and provided them with comfortable conditions.

DISCUSSION

In this research there were determined 6 types of professional motivation with various levels of effectiveness of professional activity (the list was provided by the indicators of their effectiveness): 1) motivated with a desire of public service, 2) stagnated, 3) prosocial, 4) adventures-centered, 5) deficient, 6) dependent [17]. Despite similar typologies, there was a broad list of the types of negative motivation. Moreover, there were determined the types such as stagnated, adventures-centered, deficient, and dependent. However, the stagnated type occupied medium step between highly effective and medium effective types but in the developed typology it was included in the type with negative motivation. It was connected with the fact that servicemen who were not satisfied with their profession did not prolong their contract. Thus, the research by Harrington, Bean, Pintello, and Mathews (2001) distinguished that the personnel of military sphere were more likely to change their work if they were emotionally exhausted, had a lower level of internal satisfaction with their work, satisfaction with their salary as well as possibilities to be promoted at service.

Distinguished types, their descriptions, and structure of motivation did not contradict the regulations related to the relations between public service motivation (PSM) with effective work and its average self-efficiency. In the conclusion, there were added existing relations of autonomous and controlled motivation with productive activity. The received results would be used for further development of those regulations.

By the results presented in the works by Miao, Eva, Newman, and Schwarz [18]; van der Voet, Steijn, and Kuipers [19], Breaugh J, Ritz A, and Alfes K [9] the public service motivation (PSM) was considered as one connected with a high level of effectiveness with a desire to be developed, to get satisfaction with their work, with a decrease of task complications up to the level which correlated with their ability to live with their values and believes. However, the received structural motivation of servicemen related to PSM gave the possibility to determine existing mechanisms of self-motivation of those who had PSM which connected and described those earlier distinguished regulations. Thus, firstly, there is the structural motivation was conducted through the process of connection of algorithmization of their work (easiness and generalization) and satisfaction with work. Secondly, the structure of motivation of this type of satisfaction with main needs was performed not only at the expense of chosen profession but also by its content. It could prevent corruption – situations when the end justified the means and when their priorities were set above the priorities of others. Personal and professional development, obtaining the social status also happened by the content and aims of professional law enforcement officers. Thus, namely the content of the profession which was connected with public service provided the limits of development and the search of resources which made it impossible to refuse this way of development. Such a structure of motivation supported self-realization and a high level of activity.

The structure of motivation of the stagnated type gave the possibility to broaden the view concerning average relations of PSM and productivity of activity with the psychological mechanism of self-efficiency. Thus, Schott, Neumann, Baertschi, and Ritz [10] pointed out that policemen who did not get any feedback lost their confidence in their ability to realize the motives of PSM. Because of the feeling of disability (for example, when individuals who committed crimes are set free in the courtroom) PSM is considered to be a general type of motivation related to work with limited behavioral consequences. Other than that, the received data related to the structure of motivation of the stagnated type proved the necessity of paying attention to another side of such averaging. When previous achievements which reflected on self-perception and sometimes even ruined it (for example, formed inadequately overstated self-estimation) prevented them from development and were potentially dangerous for law enforcement officers' productivity.

The research by Schott, Neumann, Baertschi, and Ritz [10] also proved that prosocial motivation differed from PSM with their orientation on the individuals and groups which were involved in the direct contact, or on the organization-employer. It lived on the feedback of those who were helped with senses of gratitude as well as with emotional appeal. Presented research gave the possibility to form the conclusion that those peculiarities of motivation had their specific reflection and the structure of motivation the prosocial type differed from the type with PSM with a lower level of subordinate structure of motivation and a higher level of concreteness of motivational factors. The structure of motivation of servicemen of the prosocial type had an almost identical value of factors which described the importance of being useful in professional activity, being good at breadwinning their families, being a good colleague in service. According to the content of factors, servicemen of the prosocial type were mostly orientated on the ability not to fail their families but not on abstracted social benefit. The protection of the motherland was for them a way of overcoming their fears, etc. Such structure developed a complicated process of selection and decision-making when the situation dealt with the interests of several sides which were important for servicemen of the NGU.

It was quite interesting to compare the received results related to the adventure-centered type with the data by Lyk-Jensen and Glad [5] who determined that servicemen who were motivated with a desire to get adventures finished only secondary school and, usually, served only one year contract. The received structure gave the possibility to conclude that servicemen of this type were not self-sufficient and thus, they required the surrounding which made their lives eventful. They did not want to change by the requirements of the profession, instead, by any means (manipulations), they wanted to join the process of performing those aspects of professional activity which gave the possibility to satisfy their desire to work.

American researchers figured out that military service was mostly joint by Afro-Americans, indigenous Latin Americans, and rarely those people who had good school grades, planned to enter college, and whose parents had higher education [2]. This tendency was strengthened after the “Desert Storm”. Thus, the candidate for lower positions who entered the military service was motivated with salary (benefits), was married, had basic education, and did not get secondary education [4]. However, Asoni, Gilli, Gilli, and Sanandaji [20] denied the theses that the American Army was hired by the Army of poor people which was used by the critics of the US external policy. They determined that despite generally accepted ideas American servicemen did not recruit primarily people with socially and economically dysfunctional layers of society. Technological, tactical, operational, and doctrinal changes led to the changes in personnel demand. As a result, according to various indicators such as family income, family wellbeing, as well as cognitive abilities servicemen on average, had identical or better indicators as civilians had. In this research the deficient type included a quarter of respondents, and, at first sight, the problem was not in the fact that they had lower education and were less confident in their abilities and skills, the problem was in the fact that even having a desire to work, to put huge efforts, and to change their motivation was weakly connected with direct content of military profession. For them, this profession was a kind of means but not an independent value.

Thus, the military profession could be substituted with any other profession which was more prospective having identical requirements for the candidates. Accordingly, they wasted efforts in the process of acquiring a profession, were not confident that servicemen would not substitute their military profession as soon as possible with the profession which was considered to provide them with better prospects.

A range of studies which included the comparison of autonomous and controlled motivation related to work satisfaction and desire to dismiss [21] being exhausted and belonging [22], being at the workplace [7], having the feeling of organizational support, positive worries, and level of communication [8].

The conducted research demonstrated that the type with the lowest level of activity effectiveness had features of dependent and controlled motivation.

The analysis of the structure of its motivation showed that profession selection and realization of the aims of professional activity of the representatives of that group were dependent on the satisfaction of personal including antisocial requirements.

They wanted to fulfill their internal lives with positive worries at the expense of external stimulation, so-called "belonging to the interesting surrounding".

The process of professional activity did not provide them with satisfaction, however, they had to deal with it to get financial benefits.

Their motivation was directed to the organization of the professional activity which did not disturb their internal emotional lives, did not bring them problems, and provided them with a comfortable environment.

CONCLUSION

The conducted research proved that motivation of servicemen could be appropriate to learn connecting the theory of public service motivation (PSM) with self-determination theory (SDT). That gave the possibility to describe not only the distinguished types of professional motivation of servicemen but also specific peculiarities including self-motivation of the representatives of this type which was run with public service motivation; "rest on laurels" of the stagnated type; problems with selection of prosocial type for whom profession, motherland, and friends had big value; tendency to manipulate to get an access to desired aspects of professional activity of the type which was adventure-centered; absence of sincere interest in military profession of the deficient type which could substitute it with more prospective work having identical requirements for the candidates; attitude to profession as if it was a kind of means of satisfaction of demands of their emotional lives of the dependent type.

The prospects of further studies

It was distinguished to be prospective to develop or standardize existing methods which correlated with the theory of public service motivation (PSM) and self-determination theory (SDT) to estimate the motivation of servicemen.

Conflicts of interest

The authors declare that there are no conflicts of interest.

Abstract: *The cytogenetic aberrations induced by doxorubicin (DOX) may be influenced by diet. Investigation regarding effects of low doses of DOX on chromosomal aberrations frequency in mice bone marrow. The study explored a possible relationship between diet, follow-up period, and cytostatic doses. Four mice groups received normal or high-fat (pork) diet. At the beginning of the 8th day mice from each group received a single intraperitoneal injection with DOX (dose range: 1.7-7.7 mg/kg b.w.) or isotonic saline solution (0.02 mL/g control mice). In the 10th (groups I, II) and 14th (groups III, IV) days from the beginning of the experiment, the mice were euthanized and chromosome aberrations were tested in bone marrow cells. The body weight of all mice who received DOX decreases, especially at higher doses. In the first three days post-injection, weight loss percentage was significantly influenced by DOX doses and/or type of diet ($p<0.003$). The interaction between the type of diet and DOX doses was not statistically significant in the follow-up period (p interactions >0.05). DOX doses were able to increase the frequency of chromosomal aberrations. DOX acts as a potent inductor of cytogenetic aberrations in bone marrow cells, regardless of the type of diet.*

Keywords: *mice, animals, injections, intraperitoneal, cytostatic agents, Doxorubicin, chromosome aberrations*

INTRODUCTION

Doxorubicin (Adriamycin, DOX) belongs to the anthracycline family of antitumor antibiotics which is prescribed for several decades in a variety of tumors [1-3]. Doses used for chemotherapy can determine serious, multiorgan or systemic, side effects in many patients [1,4] and in animal models of chemotherapy [5,6]. Most specialists consider that its antineoplastic and cytotoxic effects are the consequence of the drug's insertion between DNA strands base pairs (thus interfering with replication and gene transcription), inhibition of topoisomerase II (which predisposes to single and double-strand breaks) [7,8] and generation of reactive oxygen species (ROS) [9-11].

The DNA damage induced by this drug seems to affect preferentially some tissues (e.g. cardiac myocytes) [10,12] and it can represent an early event in doxorubicin-induced death, at least for some types of cells [13,14]. All these effects can be influenced by different factors, doses, rhythms, and routes of DOX administration [15].

Currently, studies performed on animals explore the effects of diet on DOX-side effects. Thus, long-term milk or kefir ingestion performed on old male Sprague Dawley rats may be helpful before and during DOX treatment [16]. Moreover, creatine is involved in managing Dox-induced skeletal muscle side effects [17]. Regarding the fat diet, experimental results revealed that switching to a low-fat diet 1 week before and during DOX treatment, may attenuate the DOX-increased cardiotoxicity [18]. Instead, the high-fat diet may decrease the efficacy of treatment with DOX [19].

Moreover, a hypercaloric diet will not affect only the doxorubicin efficacy, but also has a negative impact on the human body, leading to various human and animal pathologies [20-25].

Taking all these aspects into consideration, our study aimed to test the effects of low-dose DOX on the frequency of chromosomal aberrations in mice bone marrow, and whether these are influenced by diet and follow-up period.

DOX as a chemotherapeutic agent has various side effects in human and animal models. Therefore, the main aim of our study was to explore the effects of low doses of DOX on male mice fed with normal food of pork cracklings (PC).

MATERIALS AND METHODS

Animal care and doxorubicin treatment

Eight to nine weeks old BALBc male mice weighing 21.33±2.19 g were included in this study. They were accustomed to their environment for at least 10 days before the initiation of the experiment. During the experiment, the mice were maintained in the National Institute of Research and Development for Food Bioresources facility, in rooms with 20–24°C, 55–65% humidity, on a 12:12-h dark/light cycle. Mice were housed 2 in plastic cages. They received ad libitum a commercial pelleted food and filtered drinking water. The food and water were changed every other day throughout the experiment. During the experimental period, the hygienic conditions were kept constant. All mice were weighed on the 1st, 8th, and 10th day of the experiment; the mice from groups III and IV were also weighed on the 14th day (Table 1).

Table 1: Study design. NF – normal food, PC – pork cracklings

Days	1-7	8	10	14
Intervention	**Diet**	**Injection**	**Euthanasia**	**Euthanasia**
Groups	NF	i.p.	Group I	Group III
	PC	i.p.	Group II	Group IV

On the first day of the experiment, mice were distributed into 2 groups that received a normal diet (groups NFI, NFIII) and 2 groups that received only pork cracklings – PC (groups PCII, PCIV). Subsequently, the type of diet did not change until the end of the experiment. At the beginning of the 8th day, mice received a single intraperitoneal (i.p.) injection with DOX (2 mg/ml, Actavis). Eight mice from each group received one of the following doses of DOX: 1.7; 1.9; 2.2; 2.6; 3.1; 3.8; 5.1; 7.7 mg/kg b.w. In addition, four mice from each group were considered controls (C) and received a single i.p. injection with isotonic saline solution (0.02 mL/g). On the 10th (groups I, II) and 14th (groups III, IV) days from the beginning of the experiment the mice were euthanized (Table 1).

Cytogenetic analysis

Mice were injected i.p. with an aqueous solution of colchicine (0.05 %) two hours before euthanasia. For each mouse, both femurs were removed and the medullary canal was washed with 1.5 ml of NaCl hypotonic solution (75 mM). Bone marrow cells were re-suspended with a Pasteur pipette and then were centrifuged at 1000 rpm/10 minutes. The supernatant was discarded and the resulting sediment was re-suspended in 1.5 ml NaCl (75 mM). Cells were fixed in a fresh fixative solution (methanol: acetic acid 3:1) and after 20 min storage at 4°C the fixation step was repeated. After fixation, cells were re-suspended in a small volume of the fixative solution and were dropped onto clean slides that were dried at room temperature for 24 h. Slides were stained by Giemsa stain (4%) for 5-10 min and were subsequently washed with tap water and air-dried. Stained slides were coded and scored by light microscopy (at X100 magnification).

The structural and numerical chromosomal aberrations were counted for 100 well-spread metaphase/animal. The numerical (polyploidy) and structural chromosomal aberrations (e.g., deletions, translocations, acentric fragments, gaps, and chromosome stickiness) were counted. Some of these cytogenetic abnormalities (e.g., gaps, stickiness) were scored but they were not included in the total number of aberrations or the subsequent statistical analyses because we considered that they are not good indicators of chromosome damage.

Statistical analysis

Results are reported as means ± SE. The percentage weight gain was calculated as (weight gain/previous weight) x 100. Statistical analysis was performed using R statistical software (version 4.2.0). The cutoff point for significance was Bonferroni/Yates corrected.

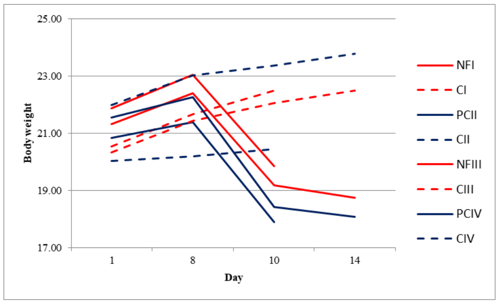
RESULTS

Body weight, diet, and treatment

The weight of mice from the four groups was similar at the beginning of the experiment (one-way ANOVA: p=0.23). The change in body weight during the experiment can be influenced by diet and the dose of cytostatic administrated

(Figure 1).

Figure 1: Average body weight of mice (g) for the groups who received DOX (DOX injection – continuous lines) or saline solution (controls – dotted lines). The type of diet is indicated by line color: red lines – NF; blue lines – PC. NF – normal food, PC – pork chops, C – control.



Thus, during the first 7 days of the experiment, the percentage of weight gain was positive but significantly lower, for mice who received PC compared with those who received NF (I, III vs. II, IV: 5.26±1.57% vs. 2.98±1.66%, $p<0.00001$). In the next three days, the percentage of weight gain for control mice remains positive and much lower in PC than in NF (3.36±0.56 vs. 1.41±0.51, $p=0.0009$).

In the interval between the 10th-14th day, this tendency was maintained, yet the differences were no longer significant (2.03±0.71% vs. 1.76±1.02%, $p>0.05$). The percentage of weight loss in the first three days after administration of DOX was influenced by either dose of cytostatic (one-way ANOVA: p=1.7E-28) (Figure 2 a) and type of diet (groups I, III vs. II, IV: -14.47±4.56 vs. -16.83±4.15, $p=0.003$) (Figure 1).

Post hoc test reveals significant differences in percentage weight loss (Tukey HSD $p<0.05$) when comparing different DOX doses, except for the two lowest doses (1.7 and 2.9 mg/kg b.w.). For the interval between days 10th-14th, this parameter was neither associated with the dose of cytostatic (groups III vs. IV: -2.25±2.88 vs. -1.83±0.98, $p=0.52$) nor with the type of diet (Figure 2 b).

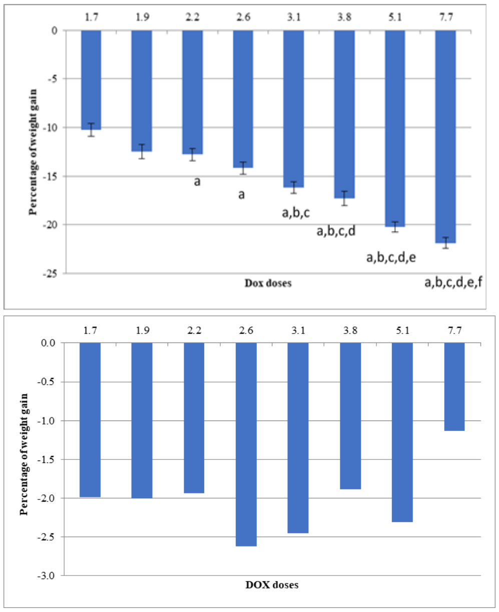
The interaction between the type of diet and DOX doses was not significant neither in the first three days after DOX administration (groups I-IV two-ways ANOVA: p interactions = 0.68) nor the following four days (groups III and IV Two ways Anova: p interactions = 0.81).

Chromosomal aberrations

The number of cytogenetic changes and deletions identified on days three (-0.76 and -0.7 respectively) and seven (-0.66) post-injection of DOX has a negative linear correlation with weight change. The frequency of cytogenetic aberrations may be influenced by DOX doses or their interaction with the type of diet, or the post-administration follow-up interval.

Doxorubicin doses between 1.7–7.7 mg/kg b.w. were found to increase the frequency of polyploidy, chromatid deletion, acentric fragments, and Robertsonian translocations (Figures 3 and 4) ($p<0.05$).

Figure 2: Percentage of weight change post-injection of DOX at three (groups I-IV) (a) or seven (groups III-IV) (b) days post-injection. Data are presented as means ± SE for both charts. p< 0.05 for overall difference (one-way ANOVA). Significant differences ($p<0.05$) identified by post hoc Tukey HSD test are indicated by letters [compared with DOX dose 1.7 (a), 1.9 (b), 2.2 (c), 2.6 (d), 3.1 (e) or 3.8 (f) mg/kg b.w.].



The total number of cytogenetic aberrations (Figure 3a), polyploidies (Figure 3b), and deletion (Figure 3c) showed significant differences between mice treated with different DOX doses (one-way ANOVA $p<0.0003$); the differences were more important when comparing values corresponding to lowest and highest DOX doses (5.1 or 7.7 mg/kg b.w., post hoc Tukey HSD $p<0.05$).

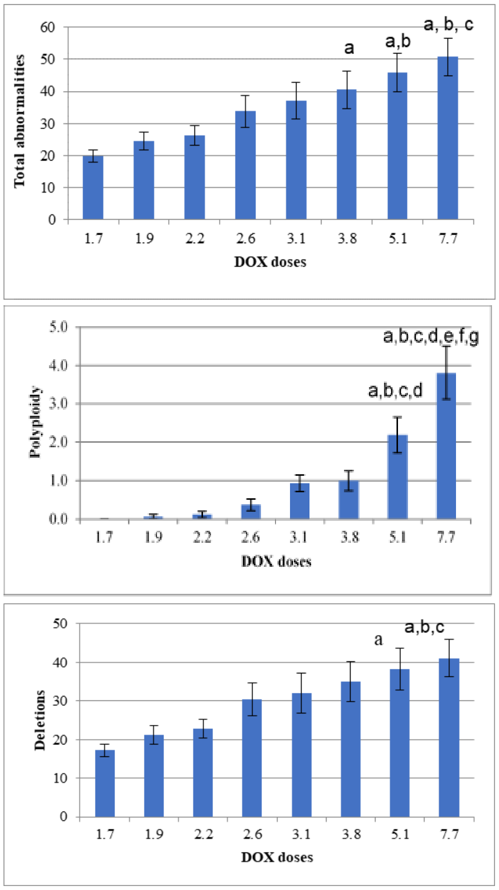
Interactions

A significant interaction between DOX dose and diet was found in the case of polyploidy (two ways Anova p= 4.5E-11); its frequency significantly increased in mice who received the highest DOX doses (5.1 or 7.7 mg/kg b.w.) and PC compared with those who received NF ($p<0.009$) (Figure 4). The interaction between DOX doses and the post-administration follow-up interval was found to not influence the frequency of cytogenetic aberration scored in this study ($p>0.05$).

DISCUSSION

Chromatin remodeling plays an essential role in cell proliferation, differentiation, and DNA repair as a consequence of gene expression regulation. Many studies on different biological models have revealed that chromatin remodeling complexes and enzymes that target histone modifications could sensitize cells to selective cytotoxic stress [26,27]. Investigation of epigenetic, cytotoxic, genotoxic, and/or mutagenic potential of cytostatics is useful for a better insight into the mechanisms of both drugs' actions and adverse effects. The reversal or accumulation of DNA lesions induced by cytostatic play an important role in cell survival and the efficiency of chemotherapy [28,29].

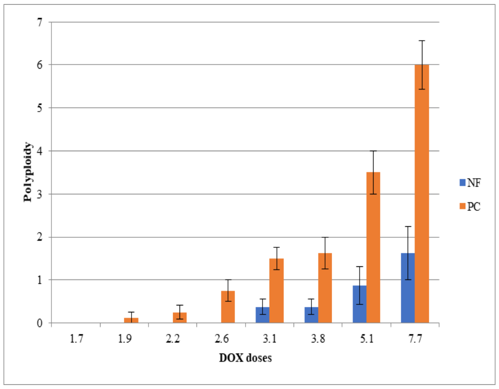
Figure 3: The distribution of an average number of cytogenetic aberrations according to DOX dose. Data are presented as means ± SE for all charts. p< 0.05 for overall difference (one-way ANOVA) were detected for the number of cytogenetic ab-errations (a), polyploidies (b), and deletion (c). Significant differences (p<0.05) identified by post hoc Tukey HSD test are indicated by letters (compared with 1.7 (a), 1.9 (b), 2.2 (c), 2.6 (d) 3.1 (e), 3.8 (f) or 5.1 (g) mg/kg b.w.).



We set out to test the clastogenic effects of eight low doses of DOX in mice bone marrow cells detected after several rounds of cell cycles.

The LD50 is related to the particularities of both expo-sure and testing systems [15]. The LD50 values for adult mice treated i.p. with DOX were estimated to be in the range of 11.98 [30] and 56.87 mg/kg b.w. [31].

Figure 4: The distribution of an average number of polyploidies according to DOX dose and type of diet. Data are presented as means ± SE for all charts. p< 0.05 for overall difference (two-way ANOVA) were detected. NF – normal food, PC – pork chops



DOX can promote localized tissue damage at the site of administration that can interfere with the absorption of the subsequent doses of the drug [32]. After exposure to high doses of cytostatic, some animals died [31] or exhibited multiple tissue toxicity [33-35]. In an attempt to mitigate some of these effects, we decided to test the impact of a single dose of cytostatic administrated i.p. to each mouse. The tested doses (the range: 1.7-7.7 mg/kg b.w.) were comparable lower to those to which human patients [36] or mice [37] are frequently exposed (20 mg/kg b.w.).

The body weight change registered during the experiment in the four groups reflects the compliance of the mice with the type of diet and the effects of the cytostatic.

In the first week of the experiment, the percentage of weight gain was positive yet much lower in mice that received PC than in those who remained on a normal diet (p=0.00001). The control mice kept this trend in the interval between the 8th-10th (p=0.0009) and the 10th-14th day (p>0.05). These results suggested that PC was not well appreciated by mice, at least in the first 10 days of the experiment (Figure 1).

The body weight of all mice decreases after DOX administration, especially at higher doses of cytostatic. In the first three days post-injection, but not in the next four days, the percentage of weight loss was significantly influenced by doses of cytostatic (Figure 2a) and/or type of diet (p<0.003) (Figure 1). The interaction between the type of diet and DOX doses was not statistically significant in the follow-up period (p interactions >0.05).

Our results are in accordance with previous studies in which i.p. administration of DOX was associated with a decrease in food and water consumption [38] and a decline of mice body weight to over three days [39]. The impact of DOX on patients' body weight was also reported [40]. The effects of DOX at the nuclear level may reflect the ability of cytostatic to alkylate DNA, to inhibit DNA denaturation, replication, and topoisomerase II activity [41].

The aneugenic and clastogenic [42,43] potential of DOX was shown in different test systems (e.g., human lymphocytes, albino mice) [44,45].

Previous studies performed on mice found that the frequencies of chromatid and chromosome type aberrations detected during the first 24h post-administration were directly correlated with DOX doses (3, 12, or 24 mg/kg b.w.) [46,47]. Also, 24 h after administration of two injections with 0.8 mg/kg DOX on consecutive days, chromosome breaks (12.6%), acentric fragments (11.6%), ring chromosomes (8.3%), Robertsonian translocations (4%) and polyploidy (2%) were identified [48].

In our study, especially in the case of higher doses of cytostatic, the frequency of chromatids breaks, polyploidy, and Robertsonian translocations had a higher frequency. Doses tested in this study were associated with a low frequency of acentric fragments. Fragmented chromosomes may be attributed to the clastogenic effects of xenobiotics on DNA strands. Differences between our results and those previously reported can be explained by the comportment of acentric fragments during mitosis and by the number of cell cycles performed by the bone marrow cells during the post-administration follow-up period (1 day vs. 3- or 7- days post-administration).

In a previous experiment with 3 or 12 mg/kg DOX, similar results for breakage (20% or 26%) and cells with translocations (0% and 1%) were estimated [49].

Some cells can become giant, polyploid, and polymorphic after exposure to a low dose of DOX (e.g., HCT116, MCF7). [47,50,51]. Twenty-four hours after 0.8 mg/kg of DOX was injected i.p. in consecutive days, the frequency of polyploidy in the bone marrow cells of mice was 0.2% (47). We observed that polyploidy was more frequent in mice that received PC vs. NF and the differences are more evident at high DOX doses (Figure 4).

Division of polyploid cells may be relevant for the generation of cancer stem cells [52] and repopulation with tumoral cells after therapy [53].

Chromosome stickiness may reflect the highly toxic effects of xenobiotics and it can lead to cell death [54-56]. In our experiment, this abnormality increases with cytostatic doses. Even though the frequency of some aberrations like gaps, complex interchange, Robertsonian translocations, and chromosomal stickiness seems to increase when reaching the end range of dosage, there are no significant results that would imply a correlation between dose and frequency for aforementioned aberrations.

Limitations of the study

Some of the DNA lesions induced by mutagens can lead to apoptosis or can be fixed. It was estimated that in 12 h after DOX treatment, some bone-marrow cells went through two cell cycles [46]. Consequently, in our experiment during the post-administration period, some cells have come through a significant number of cell cycles (up to 28). During these cycles, the chromatid deletion could be converted into chromosomal deletion and some acentric fragments can be lost. Thus, the results we have obtained using conventional cytogenetic analysis highlight only a limited spectrum of cytogenetic modifications induced by DOX.

CONCLUSIONS

A brutal shift of diet from normal feed to high fat (pork cracklings) is associated with significant weight loss. The main conclusion which emerges from our study is that treatment of mice with low drug doses significantly increases the number of chromosomal aberrations compared with controls. These aberrations are an indication of DOX toxicity for the bone marrow cells and their clastogenic impact. This clastogenic potential of DOX was not influenced by diet.

The frequencies of polyploidy and deletions were significantly higher in mice who received 5.7-7.1 mg/kg and those treated with lower doses. In addition, our results suggested that some cytogenetic damage induced by low doses of DOX can be retained even three – or seven – days post-administration.

Abstract: *The triglyceride-glucose index is a newly discovered parameter that indicates insulin resistance. This study aims to investigate the relationship between the triglyceride-glucose index and triglyceride/high-density lipoprotein ratio with glycemic control in patients with type 2 diabetes mellitus. This study was performed retrospectively in 296 patients with type 2 diabetes mellitus. Patients were divided into two equal groups according to their HbA1c levels as having good glycemic control (HbA1c 7 and below) and poor glycemic control (HbA1c above 7). Age, gender, body mass index, fasting blood glucose, HbA1c, total cholesterol, serum triglyceride level, serum HDL level, serum LDL level, triglyceride-glucose index, and triglyceride/HDL ratio were compared between the groups. Fasting blood glucose, HbA1c, triglyceride, HDL, triglyceride-glucose index, and triglyceride/HDL ratio was significantly different between patient groups with good and poor blood glucose regulation ($p<0.05$). Patients with poor glycemic control had lower fasting blood glucose, HbA1c, triglycerides, triglyceride-glucose index, and HDL values compared to patients with high triglyceride/HDL ratio and good glycemic control. There was no difference between the groups in terms of other variables ($p>0.05$). Triglyceride-glucose index and triglyceride/HDL ratio may be indicators of poor glycemic control in diabetic individuals. These indices are cheaper, universal, and easy-to-measure parameters compared to HbA1c and can be used to predict glycemic regulation.*

Keywords: *type 2 diabetes mellitus, triglyceride-glucose index, HbA1c*

INTRODUCTION

Diabetes mellitus is a global health problem whose incidence and morbidity continue to increase significantly in all countries of the world.

The most important mechanism in pathogenesis is a decrease in the sensitivity of target tissues to insulin [1]. Persistent hyperglycemia and insulin resistance are associated with long-term damage to organs, particularly the eye, kidney, nervous system, and cardiovascular system [2].

Type 2 diabetic patients have atherogenic dyslipidemia and obesity, which markedly increase the risk of coronary artery disease. Lipid profile changes in these patients increase insulin resistance and insulin resistance-related complications [3].

Regulating glycemic control and reducing insulin resistance reduces diabetic complications. Glycated hemoglobin (HbA1c) and Homeostatic Model Assessment of Insulin Resistance (HOMA-IR), which are predictors of microvascular and macrovascular complications, are the best-known parameters for retrospective long-term glycemic control and insulin resistance [4].

In several studies, indicators such as Triglyceride/Glucose index, Triglyceride/HDL ratio, body mass index (BMI), waist circumference (WC), and visceral adiposity index have shown promising results in the assessment of insulin resistance [5,6]. In addition, a recent study showed that the triglyceride-glucose index was correlated with HOMA-IR and hyperinsulinemic-euglycemic clamp test [7]. There are also studies showing the association of triglyceride-glucose index with cardiovascular diseases [8,9].

The present study aimed to examine the relationship between HbA1c, which is currently the most commonly used parameter that retrospectively shows glycemic blood control, and the triglyceride-glucose index. In addition to HbA1c, the relationship between the height-weight index and the triglyceride-glucose index was also examined.

MATERIALS AND METHODS

Study Design

The study was conducted retrospectively with a total of 296 patients with diabetes mellitus 2 who applied to the Internal Medicine outpatient clinic of Mersin Şehir Training and Research Hospital between 20.06.2021 and 20.06.2022. Patients with type 2 diabetes mellitus were selected from those who met the American Diabetes Association criteria. Patients with coronary artery disease, cancer, rheumatologic diseases, type 1 diabetes mellitus, pregnant women, patients with chronic kidney disease, patients with chronic liver disease, patients with autoimmune diseases, patients with hypothyroidism or hyperthyroidism, patients receiving anti-hyperlipidemic therapy, and patients with diabetic complications were excluded.

Demographic data of patients such as height, weight, duration of diabetes, age, and smoking status were obtained from the electronic information system. Body-mass index (BMI) was calculated by weight in kilograms divided by the square of height in meters. Regarding previous studies, the TyG index was calculated separately for each individual with the formula = ln [fasting TG (mg/dL) x fasting glucose (mg/dL)/2] [6,10]. Serum triglyceride level (mg/dL) was divided by serum HDL level (mg/dL) to obtain the Triglyceride/HDL ratio (THR). Fasting plasma glucose, HbA1c, and lipid profile were studied from venous blood samples obtained after fasting for at least 8 hours.

The 296 patients included in the study were divided into two equal groups: patients with good glycemic control (N=148, HbA1c:7 and below) and patients with poor glycemic control (N=148, HbA1c above 7). Age, gender, duration of diabetes, smoking status, body mass index, fasting blood glucose, HbA1c, total cholesterol, serum triglyceride level, serum HDL level, serum LDL level, triglyceride - glucose index, and triglyceride/HDL ratio were compared between the groups.

Ethics committee approval was obtained from Mersin University Ethics Committee before starting the study (dated 20.07.2022 and numbered 2022/491).

Statistical Analysis

Shapiro-Wilk test was used to test whether the variables conformed with normal distribution. Normally distributed variables were presented as mean±standard deviation and an independent sample t-test was used for comparisons between two independent groups. Non-normally distributed variables were presented as median (minimum-maximum). Mann-Whitney U test was used to compare non-normally distributed variables between two independent groups and the Kruskal Wallis H test was used for comparisons between three independent groups. Categorical variables were presented as frequency and percentage values (n(%)) and the Pearson chi-square test was used for intergroup comparisons.

Statistical analyses were performed in IBM SPSS Statistics 22.0 program. P<0.05 was accepted as statistically significant in all analyses.

RESULTS

A total of 298 patients were included in the study. The median age was 57 (33-75) years in the good glycemic control group and 56 (27-75) years in the poor glycemic control group. Basic demographic data and biochemical blood parameters of the patients included in the study are shown in Table 1.

Although the duration of diabetes was less than 20 years in both groups, there was a statistically significant difference between the groups (P <0.001). There was no statistically significant difference between the good and poor glycemic control groups in terms of gender and age (P= 0.201, 0.390). There was no statistically significant difference between the two groups in terms of smoking (P=0.118). No statistically significant difference was found between the two groups in terms of body mass index (P=0.118).

DM duration, fasting blood glucose, HbA1c, triglyceride, HDL, triglyceride-glucose index, and triglyceride/HDL ratio was significantly different between the patient groups with good and poor blood glucose regulation (p<0.05). DM duration, fasting blood glucose, HbA1c, triglycerides, triglyceride-glucose index, and triglyceride/HDL ratio was higher in patients with poor glycemic control while HDL values were lower compared to patients with good glycemic control. No difference was found in other variables between the groups (p>0.05). Statistical results showing the differences in biochemical parameters and triglyceride-glucose index and triglyceride-HDL ratio between the good and poor glycemic control groups are presented in Table 2.

When the relationship between triglyceride-glucose index, triglyceride/HDL ratio, and body mass index was analyzed, it was found that the TyG index and THR values did not differ between the groups concerning body mass index. (p>0,05). The results of the analysis are shown in Table 3**.**

DISCUSSION

Type 2 diabetes mellitus is a global health problem whose prevalence continues to rise. Dyslipidemia and insulin resistance are the main mechanisms involved in the development of microvascular and macrovascular complications. HbA1c is still the most widely used blood parameter that retrospectively shows blood glucose regulation over the longest period. The present study aimed to evaluate various metabolic indices that may be associated with HbA1c, which may indicate glycemic control, are economical and easily applicable.

Table 1: Anthropometric Data and Biochemical Blood Tests of the Groups with Good and Poor Diabetic Control

	Well glycemic controlled group (N=148)	**Poor glycemic controlled group (N=148)**
	$\bar{X}$+SS/Median (Min-Max)	**$\bar{X}$+SS/Median (Min-Max)**
Age (year)	57 (33-75)	56 (27-75)
Gender (n, %)	Female: 83 (56%) Male: 66 (44%)	Female: 77 (52%) Male: 71 (48%)
Smoking (n, %)	No (122, 82.4%) Yes (26, 17.6%)	No (111, 75%) Yes (37, 25%)
Diabetes duration(year)	6 (1-17)	8 (1-20)
Body Mass Index (kg/m^2)	Normal 33 (22.3%) Overweight 57 (38.5%) Obese 38 (29.2%)	Normal 49 (33.1%) Overweight 50 (33.8%) Obese 49 (33.1%)
Fasting blood sugar (mg/dL)	128 (71-303)	215 (98-445)
HbA1c (%)	6.8 (5.6-7)	9.4 (7.1-14.7)
Total cholesterol (mg/dL)	194±36.55	203.52±42.79
HDL (mg/dL)	45 (27-98)	43 (25-80)
LDL (mg/dL)	109.89±27.63	111.73±36.29
Triglyceride (mg/dL)	175 (61-780)	201.5 (72-982)
Triglyceride-glucose index (TGI)	9.28 (6.62-10.69)	9.95 (8.64-12)
Triglyceride/HDL ratio (THR)	3.76 (0.3-20.53)	4.57 (1.29-28.88)

Table 2: Comparison of Biochemical Parameters Between Groups

		N	**$\bar{x}$+SS/Median (Min-Max)**	**Z/2t**	**p**
Diabetes duration	Well Regulated group	148	6(1-17)	-4,022	<0,001

Table 3: Analysis Results Showing the Relationship Between Body Mass Index and TGI and THR

		N	Median (Min-Max)	Ki-Kare	P
TGI	Normal	82	9.76 (8.25-12)	4.88	0.087
	Overweight	107	9.6 (8.38-11.44)		
	Obese	107	9.46 (6.62-11.49)		
THR	Normal	82	4.79 (1.03-28.88)	3.729	0.155
	Overweight	107	4.22 (1.47-14)		
	Obese	107	3.77 (0.3-28.88)		

Good glycemic control, i.e. an HbA1c level below 7, plays a very important role in reducing the complications of diabetes mellitus [10]. In type 2 diabetes mellitus, hyperglycemia and decreased insulin sensitivity be associated with hypertriglyceridemia and low HDL levels when blood glucose regulation is impaired. Increased plasma cholesterol ester transfer protein (CETP) increases VLDL-C levels by facilitating the transfer of triacylglycerol and cholesterol esters between HDL and LDL particles [11,12]. Increased small dense LDL is associated with increased diabetic dyslipidemia and cardiovascular complications. Estimation of small dense LDL particles is not useful in clinical practice; the triglyceride/HDL ratio may be an indirect indicator of these LDL particles [6,13].

Previous studies have shown that the triglyceride/HDL ratio is correlated with HbA1c [13,14].

One study found higher triglyceride-glucose index and lower HDL levels in patients with poor glycemic control [14]. The result obtained in the present study is similar. The group with high HbA1c levels, the poor glycemic control group, had a higher Triglyceride-glucose index and higher triglyceride-HDL ratio compared to patients with good glycemic control (P<0.001). Similar to the other study, HDL level was significantly lower in patients with poor glycemic control in the present study [14]. Low HDL levels may be the result of increased oxidative stress associated with impaired glycemic control.

Poor glycemic control is known to increase microvascular and macrovascular complications of diabetes. Triglyceride-glucose index and triglyceride/HDL ratio are correlated with HbA1c and thus may be predictive markers of complications in diabetic patients. In a study on this subject, triglyceride/glucose index was shown to be associated with cardiac autonomic neuropathy [15]. Another study in hospitalized diabetic patients showed that nephrotic and vascular complications were associated with elevated triglyceride-glucose index [16]. Other studies have shown that the triglyceride-glucose index is higher in patients with diabetic nephropathy, retinopathy, and coronary artery disease [17,18]. Since patients with known diabetic complications (diabetic retinopathy, nephropathy, coronary artery disease, diabetic neuropathy) were excluded from the present study, it can be concluded that triglyceride-glucose index and triglyceride/HDL ratio in correlation with HbA1c is already high even before diabetic complications occur. This group of patients should be monitored more closely for the occurrence of diabetes complications. However, there may be possible micro-complications and atherosclerotic processes that have not been evaluated. Further studies may clarify this subject.

In the present study, the relationship between triglyceride-glucose index, triglyceride/HDL ratio, and body mass index was also evaluated. In both groups, patients were divided into three sub-groups according to body mass index: normal weight (body mass index of 18.5 and below), overweight (body mass index of 25-29.9), and obese (body mass index of 30 and above). When the relationship between triglyceride-glucose index, triglyceride/HDL ratio, and body mass index was analyzed, it was found that the TyG index and THR values did not differ between the groups concerning body mass index. (p>0,05). This result suggests that the triglyceride-glucose index and triglyceride/HDL ratio are not associated with obesity. That is, they are correlated with insulin resistance but not with body mass index. A previous cohort study has also shown that the triglyceride glucose index is associated with the development of diabetes in young, non-obese individuals [19]. Considering the relationship between the triglyceride-glucose index and insulin resistance, the TyG index is expected to be higher in obese individuals compared to non-obese individuals. Another study suggested that the TyG index in non-diabetic individuals can be used as a diagnostic criterion for identifying metabolically obese but normal-weight individuals [20]. In contrast to our results, another study in the literature showed that the triglyceride-glucose index was correlated with the body mass index in diabetic individuals [14]. Further investigations are needed to explain why the results are not similar in diabetic individuals.

There were two important limitations in this study. The study was conducted retrospectively and the number of patients was relatively small.

In conclusion, triglyceride-glucose index and triglyceride/HDL ratio may be indicators of poor glycemic control in diabetic individuals. These indices are cheap, universal, easily accessible parameters similar to HbA1c and can be used to predict blood glucose regulation. In addition, although these two indexes were associated with insulin resistance, they were not found to be associated with the body-mass index in diabetic individuals. Further studies are needed to clarify and validate the results. Since patients with known diabetic complications were excluded from the present study, it can be concluded that the triglyceride-glucose index and triglyceride/HDL ratio in correlation with HbA1c is already high before diabetic complications occur. This group of patients should be monitored more closely for the occurrence of diabetes complications.

Abstract: *Background: The 12-lead electrocardiogram (ECG) is an extremely useful tool for analyzing cardiac arrhythmias and numerous ECG algorithms have been developed to predict the origin of right ventricular outflow tract (RVOT) arrhythmias. Aim: To determine if using complex, time-consuming analysis, and difficult-to-memorize ECG algorithms is feasible and preferable before the ablation procedure when compared with the use of multipolar mapping catheter use during the ablation procedure. Methods: 47 consecutive patients admitted for radiofrequency catheter ablation of idiopathic PVC were included prospectively in this study. Of the algorithms selected for comparison, three have a memorable design and easy applicability (Dixit, Joshi, Pytkowski) and the fourth has a complex, detailed design and is more difficult to memorize (Zhang). Results: The greatest accuracy was observed for the algorithms proposed by Dixit and Pytkowski – 92. 3%. However, when the algorithms were compared for their accuracy, specificity, and sensitivity, no significant differences were found (p=0. 96). Conclusions: 3-D guided mapping using a conventional ablation catheter in a narrower, precise area of interest in the RVOT, based on ECG algorithms is not inferior compared to the multielectrode catheter mapping in the whole RVOT, in terms of mapping time, total procedural time, and radiofrequency application time.*

Keywords: *electrocardiogram (ECG) algorithm; multielectrode mapping catheter; premature ventricular contraction (PVC) ablation; right ventricular outflow tract*

INTRODUCTION

Idiopathic ventricular arrhythmias originating in the right ventricular outflow tract (RVOT) represent 10% of all ventricular tachycardia (VT) admissions [1,2]. The most common presentation scenario is represented by frequent premature ventricular complexes (PVC) [3], but non-sustained or sustained ventricular tachycardias are other scenarios. Ventricular arrhythmias may cause heart failure and ventricular dysfunction [4]. PVCs originating from the RVOT pre-sent on 12 lead electrocardiogram (ECG) had a left bundle branch block (LBBB) morphology and an inferior axis. The exact cut-off of ventricular burden that causes PVC-induced cardiomyopathy is not yet known. Several studies showed a correlation between PVC burden and the development of cardiomyopathy [5,6]. Baman's study [6] revealed that in patients with normal LV dimensions and systolic left ventricular (LV), a PVC burden cut-off of 24% may identify the patients at risk to develop left ventricular (LV) dysfunction.

The most common site of origin of RVOT arrhythmias is below the pulmonary valve, in the anterior septal region [7]. Less common sites of PVC are found in the right ventricular free wall, posterior septal area, and other rare areas [8,9,10]. The current guidelines for symptomatic patients with RVOT arrhythmias, recommend catheter ablation as first-line therapy [11,12]. In experienced centers, for patients without structural heart disease, the acute success rate of catheter ablation is usually high, >95% [13,14,15]. It is paramount to correctly predict the precise origin of RVOT arrhythmias to establish the appropriate ablation approach before the procedure. As a 12-lead electrocardiogram (ECG) is an extremely useful tool for analyzing cardiac arrhythmias, numerous ECG algorithms have been developed to predict the origin of RVOT arrhythmias [16-27].

The major endpoint of this study was to evaluate the differences between mapping the RVOT arrhythmias using a 3-D electroanatomical system as Ensite (Abbott Laboratories, Abbott Park, IL, USA) and a quadripolar catheter (Abbott Laboratories, Abbott Park, IL, USA) only in the region of interest based on ECG algorithms shortens significantly the mapping time, the total procedural time, the radiofrequency application time,. when compared to the use of a multipolar mapping catheter (16 electrodes) (Abbott Laboratories, Abbott Park, IL, USA) in the entire RVOT.

Another endpoint was to determine if using complex, time-consuming analysis, and difficult-to-memorize is feasible and preferable instead of determining a wider location of RVOT ectopies (septal or free wall location) before the ablation procedure. Other objectives were to evaluate the concordance between the arrhythmia location based on each algorithm and the location obtained on the 3-D mapping system and to define the level of accuracy of each algorithm used in our study.

MATERIALS AND METHODS

Study population

Between January 2019 and October 2022, 47 consecutive patients admitted to two different centers for radiofrequency catheter ablation of idiopathic PVC were included prospectively in this study. PVCs with LBBB morphology and an inferior axis were documented for all patients. Usually, symptomatic patients have a high PVC burden (>10000 PVCs/24h). Because symptoms are not found exclusively in this category, patients with a reduced PVC burden (5000-10 000/24h) are frequently highly symptomatic and warrant ablation[28]. In this study, we included symptomatic with PVCs refractory or intolerant to an antiarrhythmic drug (beta-blocker and/or at least one class IC anti-arrhythmic agent), with a ventricular burden above 5% on a 24-hour Holter monitoring. All patients presented normal left ventricular ejection fraction.

Of the algorithms selected for comparison, three algorithms have a memorable design and easy applicability (Dixit [26], Joshi [3], Pytkowski [27]). The fourth algorithm has a complex, detailed design and is more difficult to memorize (Zhang [24]).

Evaluated algorithms

1. The Dixit algorithm (2003) evaluates the presence or the absence of “notching” in leads II, III, and aVF, and pre-cordial transition (R ≥ S at or beyond lead V4) to predict the arrhythmia origin. QRS polarity in lead aVL is further assessed to determine arrhythmia locations in the anterior to the posterior plane.

2. The Joshi algorithm (2005) is based on three criteria for differentiating the free wall from septal wall origin (presence or absence of R-wave “notching” in inferior leads, a QRS duration ≥140 ms, an R/S ratio ≤1 in lead V3). According to the QRS polarity in lead I, the anterior or posterior location of arrhythmias is determined. Next, the QRS polarity in aVL lead determines a cranial versus a caudal origin.

3. The Zhang algorithm (2009) allows the location of the ventricular arrhythmias in four different sites (RV septal, or free wall origin, near the His, LV). It begins with the determination of the QRS morphology and axis. LBBB morphology with the inferior axis suggests an RVOT origin. The transitional zone in V4, the R wave duration index, the R/S amplitude index, and RR’/RSR’ pattern in lead aVL are evaluated. The PVC-QRS duration/the QRS duration of the preceding sinus beat and QRS pattern in lead I am also evaluated. Arrhythmia origin is further described as anterior, posterior, and mid-region.

4. The Pytkowski algorithm (2013) uses RVOT arrhythmia location in one of the 9 sub-regions created by 3 vertical and 3 horizontal zones. It starts by evaluating the presence or the absence of “notching” in leads II, III, and aVF. A low R wave amplitude in the inferior leads suggests a free wall origin. RVOT is next divided into 3 vertical zones (posterior to anterior) based on the lead I polarity. Then, 3 horizontal zones are defined, depending on the transitional zone in the precordial leads, with the horizontal intermediate zone (R[r] = S[s] in V4) occupying a zone in the median part of the RVOT which delineates the superior and the inferior zones.

All the ECG tracings were analyzed at a paper speed of 25 mm/s and were reviewed by two experienced electrophysiologists to locate the origin of the arrhythmia based on the 4 presented algorithms. Each electrophysiologist used ECG assessment one consecutive algorithm for every consecutive patient. Furthermore, based on the precise or wider location obtained from ECG evaluation, the ablation procedure was performed using the same 3-D mapping system, mapping, and ablation catheter. The algorithm used for evaluation, the time from the beginning till the end of the mapping with the multielectrode catheter and next with the mapping and ablation catheter, the success rate, procedural time, and radiofrequency application time during ablation procedures were registered for each patient.

Based on Dixit and Zhang algorithm, a less precise sub-localization in the RVOT was performed – septal vs free wall and on the horizontal plane (posterior, median, and anterior zones). When Zhang or Pytkowski’s algorithms were used, the location was identified in one of the nine regions of the RVOT divided by 3 vertical and 3 horizontal lines.

Electrophysiological procedure

The anti-arrhythmic therapy was interrupted for all patients at least five half-lives before the procedure. Spontaneous PVC at baseline and during intravenous isoprenaline (1-4 µg/min) infusion were recorded. A multipolar (16 poles) electrode catheter was inserted into a femoral vein and positioned in the RVOT. The 3D geometry of RVOT was created by navigating the mapping catheter within the RVOT using the non-contact electro-anatomical mapping system. To identify the earliest activation (EA) site, a broad color setting with a high pass filter set at 2 Hz was used. The EA site was identified by stepping further back in time where the red color zone shrinks down to the blue. For each patient, the EA site obtained from the mapping with the multi-polar catheter was noted, as well as the time from the insertion of the mapping catheter in the RVOT until the final definition of the earliest activation zone. Next, an eight-French quadripolar catheter with a 3. 5 mm distal electrode, sensor-enabled interelectrode spacing of 1-4-1mm, and a flexible tip (Abbott Laboratories, Abbott Park, IL, USA) was placed in the RVOT for mapping the earliest activation zone in the region of interested obtained from the ECG algorithm. The time from the insertion of the ablation catheter in the RVOT until the final definition of the earliest activation zone was also noted. Unipolar electro-grams at this site were reconstructed. The presence of a QS morphology was used as an additional criterion for the EA site.

For the Ensite system, several modules can be used to facilitate the localization of ventricular arrhythmia origin - Template Score Matching (Figure 1, Figure 2) and Real Time PVC Map Score. Template Score Matching analyses the QRS morphology of the clinical PVC in all 12 leads ECG during mapping and creates a compatibility score for the PVC. This way, all PVCs that are not in the interest zone are eliminated, either non-clinical PVC or PVC induced by the catheter movement.

The filter settings for the intracardiac electrograms were set at 30 –500 Hz. The pacing was performed at twice the diastolic threshold with a programmable stimulator using stimuli with a duration of 2ms. Pace mapping for each of the targeted sites was also performed to ensure at least 11 of 12 matching on the 12-lead ECG.

Concordance between the earliest activation zone obtained from the multielectrode catheter and the mapping and ablation electrode for each patient was evaluated. In the case of concordance, the earliest activation site was targeted by radiofrequency catheter ablation. In case of mismatch, radiofrequency energy was delivered through the ablation catheter in temperature-control mode (Stockert, Biosense Webster, Diamond Bar, CA, USA) in the earliest activation zone obtained from the multielectrode catheter. The power output was titrated to as high as 40 W to achieve a target temperature of 48°C for 60 – 120 s.

Figure 1: 3-D reconstructed image of the right ventricular outflow tract with activation map revealing the origin of ventricular in the white zone (with the red dots added) in the septal area of RVOT. The compatibility score of 100% and the earliest activation time (LAT) of 24 ms (the time from the earliest ventricular EGM to the onset of QRS) are displayed in the inferior part of the image. In the right panel, the 12 lead ECG shows a PVC characterized by an LBBB morphology with late transition in V4 and R/S ratio > 1 in lead II, III, and AVF. The presence of QRS notching and the lower R wave amplitude in the inferior leads is highly suggestive of a free wall origin.

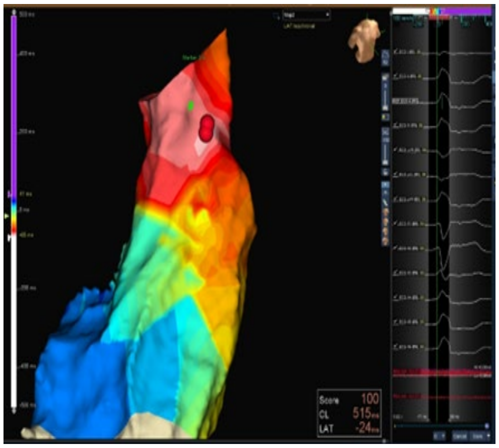

Figure 2: 3-D reconstructed image of the right ventricular outflow tract with activation map revealing the origin of ventricular ectopy in the white zone in the septal area of RVOT. The compatibility score of 99% and the earliest activation time (LAT) of 21 ms (the time from the earliest ventricular EGM to the onset of QRS) are displayed in the inferior part of the image. In the right panel, the 12 lead ECG shows a PVC characterized by an LBBB morphology with late transition in V4 and R/S ratio > 1 in lead II, III, and AVF. The lack of QRS notching and a higher R wave amplitude in the inferior leads suggest a septal origin.

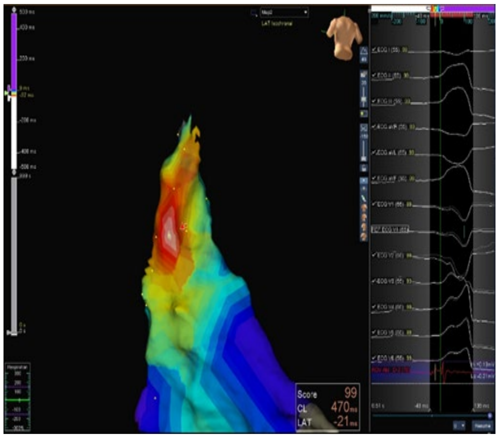

An observational period of 30 min was applied for all patients. In case of incomplete elimination of VAs, surrounding sites were further investigated by activation and pace map-ping to find alternative ablation sites. Next, subsequent ablations were applied to those sites. The ablation procedure was considered successful if clinical PVC disappeared during RF and didn't reoccur within 30 minutes after the last RF application, and if PVCs were non-inducible after Isoproterenol infusion (1-10 µg/min) [29,30].

Based on the 3D electroanatomical non-contact mapping, RVOT was divided through vertical and horizontal imaginary lines into nine distinct regions to facilitate the description of the origin of PVC based on the successful ablation site.

Statistical analysis

For data analysis, IBM SPSS Statistics for Windows (version 20. 0; IBM Corp. , Armonk, NY, USA) was used. Continuous variables are presented as median and mean ± standard deviation (SD). Categorical variables were presented as counts and percentages.

RESULTS

47 patients with RVOT arrhythmias were enrolled in this study. Patient clinical characteristics are presented in Table 1. Ablation was delivered at 14 free wall sites and 33 septum sites.

The 3D electroanatomic maps were created for all patients. The precise origin of RVOT was identified as it is presented in Table 2. The RVOT chamber was correctly identified by the evaluators in 47/47 (100%) patients. Furthermore, the concordance between the origin obtained from the multielectrode catheter also targeted for ablation, and the origin obtained by the mapping and ablation catheter guided by the ECG algorithm was evaluated. The results are presented in Table 3.

Table 1: Clinical characteristics (PVC, premature ventricular contraction; LVEF, left ventricular ejection fraction)

Age (years; median)	42. 76
Female/ Male (n)	27/20
PVC burden (%; median)	17. 95
LVEF (%; median)	62. 1
Use of antiarrhythmic drugs(%) - Beta-blockers - Class I C	76. 59% 44. 68% 31. 91%

Table 2: Localization of arrhythmia in RVOT based on mapping with the multielectrode catheter when performed by both electrophysiologists (EP1 and EP2).

Location in RVOT	EP1	EP2	Total
Free wall	6	8	14
Anterior	1	0	1
Mid	1	2	2
Posterior	4	6	11
Septal wall	17	16	33
Anterior	8	7	15
Mid	2	2	4
Posterior	7	7	14

Table 3: The concordance between the origin obtained from the multielectrode catheter, also targeted for ablation and the origin obtained by the mapping and ablation catheter guided by ECG algorithm.

Algorithm	Electrophysiologist 1 Concordance - number of patients/percentages	Electrophysiologist 2 Concordance - number of patients/percentages	Concordance - number and percentage in our study
Dixit	5/6 patients 83. 33%, P=0. 68	6/6 patients 100%, P=0. 54	11/12 patients 91. 6%, P=0. 77
Joshi	4/6 patients 66. 66%, P=0. 51	5/6 patients 83. 33%, P=0. 68	9/12 patients 75%, P=0. 75
Zhang	4/5 patients 80%, P=0. 42	3/6 patients 50%, P=0. 55	7/11 patients 63. 63%, P=0. 94
Pytkowski	5/6 patients 83. 33%, P=0. 51	6/6 patients 100%, P=0. 55	11/12 patients 91. 66%, P=0. 96
Total	18/23 patients	20/24 patients	38/47 patients 80. 85%, P=0. 88

Acute procedural success was achieved for 45 out of 47 patients (95. 74%). Failure of RF ablation was observed in 2 out of 47 patients, both patients in the concordance origin group. The diagnostic accuracy evaluations showed that the greatest accuracy was observed for the algorithms proposed by Dixit and Pytkowski – 92. 3%. However, no significant differences were found when the algorithms were compared for their accuracy, specificity, and sensitivity (p=0. 96). The diagnostic accuracy, sensitivity, and specificity of each algorithm are presented in Table 4.

Table 4: Accuracy, sensitivity, and specificity of each algorithm in our study

Algorithm	Sensitivity	Specificity	Accuracy
Dixit	100%	80%	92. 3%
Joshi	87. 5%	71. 43%	80%
Zhang	80%	60%	73. 33%
Pytkowski	100%	66. 67%	92. 3%

The mean time for mapping with the multielectrode catheter was 14. 89±8. 15 min, whereas the time used for mapping with the ablation catheter in the region of interest obtained from the ECG algorithms was. 12. 27±7. 70 min. The mean total procedural time was. 95. 5±24. 42 min. The mean total RF application time was 264. 46±134. 12 seconds. Ectopy recurrence during the waiting time occurred in 5 out of 47 patients (10. 63%).

DISCUSSION

The predicted accuracy of the ECG algorithms in our study varied from 73. 3% to 92. 3%. The accuracy of algorithms was similar to the results previously reported [9-27] despite the differences in the population, and the heterogeneity between the assessors in our study and the developers of algorithms, a narrower sub-localization of the arrhythmias compared with algorithms differentiating only septal from the free wall and a more complex design of the Zhang algorithm.

Though the diagnostic accuracy was similar for the algorithms proposed by Dixit and Pytkowski – 92. 3%, the Pytkowski scheme allows a more precise location, not only septal vs free wall location, but also a more exact location in the horizontal and vertical plane.

Several major issues were observed when comparing the Dixit algorithm from our study and the Dixit publication. Dixit algorithm predicts the arrhythmia origin based on pace mapping and not based on activation maps or a combination of activation and pace mapping as it is known that pace mapping in RVOT exhibits a lower spatial resolution (2 cm). Secondly, our study allowed arrhythmia localization in one of the 9 regions of RVOT, while the Dixit algorithm is refined to 6 zones.

One major issue was also detected when comparing our evaluation based on the Pytkowski algorithm with the one from the Pytkowski study In the Pytkowski study, the precise location of arrhythmia was fluoroscopy only based, without the use of 3-D mapping.

The analysis of mapping time, total procedural, time, and RF application time performed in the concordance and non-concordance origin groups of the multielectrode catheter and ablation catheter mapping showed no significant differences (p=0. 15) – Table 5. Next, the impact of ventricular burden during the procedure and especially during the mapping interval on the mapping time, total procedural time, and RF application time performed in the concordance and non-concordance origin groups of the multielectrode catheter and ablation catheter mapping, was evaluated and results are presented in Table 6.

Table 5: The impact of concordance or non-concordance origin of RVOT arrhythmia on mapping time with a multielectrode catheter, ablation catheter, total procedural time, and RF application time.

Mean time ± SD	Concordance group	Non-concordance group	P value
Multielectrode catheter mapping time	16. 29 ± 7. 97 min	11 ± 7. 46 min	0. 71
Ablation catheter mapping time	12. 94 ± 7. 08min	10. 53 ± 9. 2 min	0. 43
Total procedural time	94. 17 ± 25 min	99. 15 ± 23. 4 min	0. 67
RF application time	243. 08 ± 127. 14 sec	320. 38 ± 140. 53 sec	0. 23

The evaluation revealed that a low ventricular burden du-ring mapping is associated with a longer total procedural time (P=0. 04) and a longer RF application time (p=0. 01). These findings can be explained by a cumulation of factors. A low ventricular burden during mapping can prolong the mapping time (though statistical differences were not observed in our study). The suppression of clinical PVC during catheter manipulation during low ventricular burden can be more frequently unnoticed. The waiting period after RF application in these cases can also be prolonged, either due to early or late recurrence of PVC, either by transient suppression caused by an incomplete lesion or ablation in an adjacent zone near the real focus.

Based on these findings we can conclude that there are no significant differences in terms of mapping time, total procedural time, and RF application time when mapping is performed with a multielectrode catheter or a conventional ablation catheter in a narrower, precise area of interest in the RVOT, based on ECG algorithms.

The ECG-based algorithms for a narrower localization in the RVOT may exhibit acceptable to excellent accuracy, simplify the mapping process, reduce the procedural and RF application time, and improve clinical outcomes, resulting in greater clinical utility. Algorithms with a more elementary and easy-to-memorize design as Pytkowski can be routinely used to precisely localize the RVOT arrhythmia origin instead of other algorithms with a less precise sub-localization of arrhythmia origin.

Table 6: The impact of ventricular burden during the procedure on the total mapping time, total procedural time, and RF application time performed in the concordance and non-concordance origin groups of the multielectrode catheter and ablation catheter mapping.

Mean time	Concordance group	Non concordance group	P value
Multielectrode catheter mapping time PVC : 1- 5/ min PVC : 6-10/min PVC : >11/min	22. 14 min 15. 38 min 5. 5 min	19. 75 min 9. 75 min 5 min	0. 79
Ablation catheter mapping time PVC : 1- 5/ min PVC : 6-10/min PVC : >11/min	18. 5 min 11. 07 min 4. 2 min	19. 75 min 7. 75 min 5. 4 min	0. 7
Total procedural time PVC : 1- 5/ min PVC : 6-10/min PVC : >11/min	115. 15 min 87. 92 min 64. 66 min	105. 5 min 93. 25 min 98. 8 min	**0. 04**
RF application time PVC : 1- 5/ min PVC : 6-10/min PVC : >11/min	318. 92 sec 198. 14 sec 171 sec	362 sec 323. 5 sec 284. 6 sec	**0. 01**

Meanwhile, it is paramount to understand that the algorithms with a discriminating and stepwise analysis may lessen the inaccurate results. Detailed algorithms are not easy to remember, and the orientation of the subsequent steps can be frequently challenging. Time-consuming and complex analyses of such algorithms may be more helpful while predicting the arrhythmia location and may lead to better preparation before the procedure. Also, in our study, in case of erroneous predictions of the RVOT arrhythmia origin based on ECG algorithms, the effectiveness of ablation was not impacted, and no inappropriate approaches were detected.

Limitations

The number of patients in our study is relatively small, which may affect the results. Several limitations associated with the ECG algorithms were found both in our and other studies such as inconsistencies and heterogeneities between the assessors, the fact that some algorithms require an accurate measurement of many ECG parameters, and the lack of electronic calipers or wandering baselines [20-22]. Variable spatial relationships of the heart in the thorax and variable lead placements are prone to create inaccuracies in ECG algorithms [13,31,32]. In our study, we did not perform magnetic resonance imaging (MRI) for all patients so right ventricular dysplasia cannot be ruled out. The patients' age range was 24 to 69 years for this study, and we did not include more pediatric or older patients, thus the age-related changes of PVC morphology are not discussed.

CONCLUSION

3-D guided mapping using a conventional ablation catheter in a narrower, precise area of interest in the RVOT, based on ECG algorithms is not inferior compared to the multi-electrode catheter mapping in the whole RVOT, in terms of mapping time, total procedural time, and RF application time. In case of misleading predictions of the RVOT arrhythmia origin based on ECG algorithms, the effectiveness of ablation is not impacted.

In our study, although both Dixit and Pytkowski algorithms have the best accuracy among the evaluated algorithms, the Pytkowski scheme is more precise in localizing the RVOT arrhythmias origin, not only in septal vs free wall but also in the horizontal and the vertical plane, has a more basic and easy-to-memorize design.

Abstract: *Background: The highlighting of possible risk factors for urinary colonization in patients with obstructive urolithiasis that needed double J catheters implanted to preserve renal function. Methods: We performed a descriptive, retrospective study, carried out in the Urology Department of the Bucharest Central Military Hospital, between January 2020 and January 2022 and included 168 patients with urolithiasis who required the insertion of double J catheters. We studied the bacteriological profile, using both urine and JJ catheter samples. Results: We obtained a double J catheter colonization rate of 32% (54 patients) and 29% of urinary colonization (49 patients). The rate of urinary colonization is higher in patients with colonized ureteral catheters regardless of sex, age, and associated comorbidities. At the same time, we noticed an increased rate of urinary colonization in patients associated with diabetes, hypertension, and chronic kidney disease. Conclusions: The prevalence of urinary colonization in patients with double J catheters was 29%. The colonization of the JJ catheters, as well as the association with chronic diseases, such as diabetes, hypertension, and CKD (Chronic Kidney Disease), show an increased risk of urinary colonization.*

Keywords: *double J catheters, obstructive urolithiasis, urinary colonization, risk factors*

INTRODUCTION AND OBJECTIVES

Urolithiasis is a frequent pathology; in developed countries, its prevalence in the general population has tripled in the last 40 years. Acute Renal Colic is common in the Emergency Department, and approximately 6% of these require hospitalization due to subsequent complications [4,8].

Today we have multiple urological treatments available: extracorporeal lithotripsy, rigid or flexible ureteroscopy, and percutaneous nephrolithotomy, and their results can be improved by expulsive medical therapy and posturotherapy. Minimally invasive procedures have become common practice in urology departments, being very effective and having the advantage of rare post-procedure complications.

The method of treatment of urolithiasis depends on multiple factors: the patient's morphology and comorbidities; the size, chemical composition, and location of the calculus, urinary tract anatomy, and/or other possible complications.

In complicated urolithiasis with complete obstruction and/or secondary infection, an endo-prosthesis may be required temporarily, whatever the surgical method subsequently approached.

An ultrasound-guided percutaneous nephrostomy would be performed in case of physiological urinary drainage failure [3,6].

The urinary tract is normally sterile, except for the distal portion of the urethra. Urinary tract infections can occur through different mechanisms, but the contamination is ofte006E endo or extra-luminal. The use of catheters favors the colonization process by the means of an extracellular polysaccharide matrix to which germs adhere, resulting in a biofilm that will protect them from both defense mechanisms and microbial agents [2,5].

New methods have been constantly seeking to decrease the colonization rate of ureteral catheters by using different materials (silicone, polyethylene, polyurethane, biodegradable materials) or by covering the catheters with thin protective films (heparin, silver, polytetrafluoroethylene, antibiotics) [7].

Urinary colonization, unlike bacterial urinary infections, does not indicate systematic antibiotic treatment, even if the patient has an inserted catheter or not, is diabetic, elderly, with a neurological bladder. In special situations, antibiotic treatment is justified:

- if urinary colonization is a risk factor for morbidity and mortality: neutropenia, immunosuppressed, pregnant women;

- pre-operative: surgery and urological examinations;

- patients with joint, vascular, or cardiac prostheses that require invasive investigations;

- epidemic with multiresistant bacteria in a hospital unit.

Over time, many studies have been conducted on urinary infection and colonization [1], without looking for their prevalence amongst JJ ureteral catheter carriers, regardless of indication, comorbidities, or complications.

The objectives of the study were to identify possible risk factors of urinary colonization in patients with double J catheters inserted for complicated urolithiasis.

MATERIALS AND METHODS

This descriptive, retrospective study, was carried out in the Urology Department of the "Dr. Carol Davila" University Central Emergency Military Hospital, between January 2020 and January 2022.

The batch included 168 patients with obstructive urolithiasis who were inserted with double J ureteral catheters, regardless of sex, age, comorbidities, and complications.

Patients who did not agree to be included in the study, pregnant women (there is no integrated Obstetrics - Neonatology department within the Central Military Emergency University Hospital "Dr. Carol Davila"), and patients for whom transfer to other departments was necessary were excluded.

Preoperative biochemical evaluation and bacteriological examinations (urinary and JJ catheter sampling) were performed on nonselective media (BCP = bromocresol purple lactose and CLED = cystine – lactose – electrolyte – deficient).

It has been used as the standard method of insertion of JJ ureteral catheters - retrograde endoscopically under spinal anesthesia.

The following parameters were studied:

- sex and age;

- laterality of the catheter: right/left, both;

- associated comorbidities: general (high blood pressure, diabetes), reno-urinary (renal malformations, adenoma/ prostate cancer, bladder cancer), or immunosuppressed (grafts, Covid 19, other cancers);

- type and location of urinary infection: asymptomatic/ symptomatic, low/high;

- type and conditions of insertion of the ureteral catheter: emergency/appointment;

- indwelling time of the catheter: under/over 30 days;

- occurrence of post-stenting complications: calcifications, hematuria.

RESULTS

The study group included 168 patients, of which 101 men (60%) and 67 women (40%) with a sex-ratio M/W of 1.50. Urinary colonization is more frequent in women, 46% (31 patients) compared to 31% in men (31 patients), possibly explained by the shorter urethra in women and the proximity of the digestive flora.

The average age of the patients was 59 years, with extremes of 19 and 85 years.

The indication for the double J catheter insertion was ureteral-hydronephrosis, bilateral in 39% of cases (66 patients) and unilateral in 61% of cases (102 patients).

The distribution, from the point of view of stone laterality, was: 28% on the right (47 patients) and 72% on the left (121 patients); 52% pelvic ureteral stones (87 patients) and 48% pyelitic lithiasis (81 patients).

Many patients associated other comorbidities too (Table 1).

Table 1: Associated comorbidities with obstructive urinary lithiasis

Comorbidities	Number of patients	Rate [%]
High Blood Pressure	55	33
Diabetes	39	23
Obesity	27	16
Covid 19	18	11
Adenoma/Prostate cancer	28	17
Bladder cancer	10	6
Other cancers	7	4
Recurrent Urinary Tract Infections	49	29
CKD	32	19

Monitoring the bacteriological profile of the urine for the group of 114 patients with non-colonized catheters revealed that only 19 patients (17%) presented subsequent urinary colonization, and 83% (95 patients) remained non-colonized.

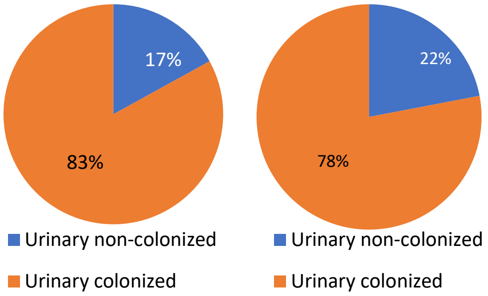
Amongst patients with colonized catheters (54 patients), only 12 (22%) remained bacteriologically negative throughout the study, regardless of comorbidities or associated complications (Table 2 and Figure 1).

The ureteral catheters colonized have a primary contributor to the pathogenesis of urinary infections, increasing their occurrence, regardless of sex, age, and comorbidities of patients in our batch.

Table 2: Urinary bacteriological profile depending on the JJ catheter bacteriological profile

Group	Number of patients	
	Urinary colonized	Urinary non-colonized
Non-colonized JJ catheters	19 (17%)	95 (83%)
Colonized JJ catheters	42 (78%)	12 (22%)

Figure 1: (a) Distribution of urinary colonization in patients with colonized catheters; (b) Distribution of urinary colonization in patients with non-colonized catheters



From a bacteriological point of view, different germs were identified, with the predominance of Escherichia Coli, and Klebsiella pneumoniae, both, at the urinary level and in the ureteral stents (Table 3).

We studied the urinary bacteriological profile in patients with urolithiasis and chronic diseases such as Diabetes, High Blood Pressure and CKD regardless of the ureteral catheters' bacteriological profile (Table 4).

Table 3: Germs identified at urinary and ureteral catheters level.

Bacterial germ	Number of patients with urinary colonized	Number of patients with JJ catheters colonized
Escherichia Coli	13	18
Klebsiella Pneumoniae	10	8
Enterococcus Faecalis	8	9
Enterobacter Cloaecae	1	2
Serratia Marcescens	1	0
Staphylococcus Hominis	3	0
Staphylococcus Aureus	1	6
Others	5	5

Table 4: Urinary profile of patients with associated chronic diseases

Associated chronic diseases	Number of patients	Urinary Colonization	
		Positive	Negative
Diabetes	39	22 (57%)	17
High Blood Pressure	55	26 (47%)	29
CKD	32	16 (50%)	16

In patients with chronic diseases such as diabetes, high blood pressure, and CKD we noticed an increased risk of urinary colonization regardless of the bacteriological profile of JJ catheters.

We noticed a higher rate of acute kidney failure in patients with obstructive urolithiasis associated with diabetes, high blood pressure, or chronic kidney failure, probably determined by the presence of secondary angionephrosclerosis.

It is already known that the immunosuppressed, pregnant women, alcoholics, and the elderly have a higher risk of bacterial colonization (urinary and catheters) regardless of associated comorbidities**.**

CONCLUSIONS

Double J (ureteral) catheter implants represent a minimally invasive alternative for deriving the upper urinary system to preserve the renal function, in case of acute or chronic, intrinsic or extrinsic obstruction, regardless of its type.

The study shows that 29% of the patients with urolithiasis carrying double J catheters have urinary colonization.

The colonization of double J catheters, regardless of the amount of time since they were inserted, plays an important role in the pathogenesis of urinary colonization.

The prevalence of urinary colonization increases with the indwelling time and especially in the case of emergency insertion of ureteral catheters.

Chronic diseases, such as Diabetes, High Blood Pressure, and CKD, are associated with increased risks of urinary colonization, requiring strict bacteriological monitoring.

Complications related to the indwelling of the double J catheter are rare and occur especially in the case of long-term indwelling (more than 30 days) and disappear with its ablation.

Abstract: *Background: Self-care behaviors are very important to control type 2 diabetes. The current study was conducted aiming at determining the effect of the educational intervention based on mobile short message service on the self-care behaviors in patients with type 2 diabetes in Khorram Abad. Methods: This study was a semi-experimental study on 191 patients with type 2 diabetes (45 cases and 45 control). Data collection tools included a demographic information form, International Physical Activity Questionnaire, Self-Care Scale, and Self-Efficacy Scale. Three to four educational messages were sent daily through mobile phones as an educational intervention. Data were analyzed with SPSS V24 at a significance level of 0.05. Results: The data analysis indicated that the average score of self-care, self-efficacy, and blood sugar was significantly higher in the case group than in the control group before and after the intervention (P<0.001). However, in terms of the physical activity variable, this relationship was not statistically significant in the case and control groups. Conclusion: Educational interventions to empower diabetic patients by strengthening their self-care can be an effective way to improve the health of diabetic patients. Therefore, it is suggested to use patient empowerment programs, especially with a self-care approach, to improve the health of patients.*

Keywords: *self-care, self-efficacy, physical activity, blood sugar, type 2 diabetes*

INTRODUCTION

Diabetes is the most common disease caused by metabolic disorders, which is mainly characterized by a chronic increase in blood sugar and disturbed carbohydrate, fat, and protein metabolism. In general, diabetes is a multifactorial disorder diagnosed by a chronic increase in blood sugar or hyperglycemia (according to diagnostic criteria) and is caused by a disorder in insulin secretion or function or both [1]. Retinal damage and blindness, peripheral neuropathy, leg pain, stroke, peripheral vascular problems, end-stage renal disease, and limb amputation are among the most serious complications of diabetes [2]. The most common type of diabetes is type 2 diabetes, which accounts for approximately 90-95% of diabetes cases and is usually associated with metabolic disorders, weight gain, and physical inactivity [3]. About 422 million people worldwide suffer from diabetes, the majority of whom live in low- and middle-income countries, and 2019, diabetes was introduced as the direct cause of 1.5 million deaths [4]. According to the International Diabetes Federation (IDF), the number of diabetic patients will reach 439 million people in 2030, and the prevalence of diabetes in developing countries will be 69% [5]. More than 3 million people with diabetes live in Iran [6]. By 2030, Iran will be one of the most prevalent regions in the world in terms of diabetes [7]. Paying attention to the chronic and costly nature of this disease for the general health of society and the creation of a large financial burden, it is essential to pay serious attention to this problem and its consequences [8]. According to the results obtained from the studies, the long-term complications of this disease, including neuropathy, nephropathy, and retinopathy can be prevented or at least the occurrence of these complications can be postponed if blood sugar is controlled [9, 10]. Many studies have found physical activity and exercise to be effective in reducing blood sugar levels and controlling diabetes [11,12]. The World Health Organization considers education to be the basis of diabetes treatment. Therefore, self-care is one of the important topics of diabetes treatment. Self-care is a learned regulation function in humans, which is based on the ability of people to perform care actions on themselves [13]. It includes the behaviors of following a proper diet, taking medicine on time, self-monitoring blood sugar, performing regular physical activity, and physical care of the feet [14]. Studies show that 67% of patients with type 2 diabetes do not monitor their blood sugar according to the recommendations. Also, only 19-30% of diabetic patients use the recommended physical activities and compliance with nutritional behaviors in these patients is 65%, and only 7% of diabetic patients fully adhere to all aspects of self-care behaviors [15,16]. Self-efficacy is also known as a strategy to improve self-care in diabetic patients, which results in self-confidence and adherence to care recommendations to control blood sugar in these patients [17].

Nowadays, to follow up and educate diabetic people, new communication systems are required to direct the focus of care and treatment from the clinic to the patient's daily life. Researchers have pointed out the use of mobile phone service as a method of education and follow-up in chronic diseases, that short message is one of the main functions of mobile phone in the education of diabetic patients [18,19].

Considering the importance of self-care in controlling the blood sugar of diabetic patients and the value of self-efficacy as one of the self-care approaches, it seems necessary to design educational interventions on the platform of mobile phones and in the form of short messages as a relatively new educational method in controlling the disease of diabetics. Thus, the present study was conducted to determine the effect of the educational intervention based on mobile phone short messages on self-care in patients with type 2 diabetes referred to the diabetes clinic in Khorramabad.

MATERIALS AND METHODS

Population of study

The present study was a semi-experimental intervention research with a pre-test and post-test design. The sample size was specified as 90 people who were selected from the research population of patients with type 2 diabetes referring to the diabetes clinic in Khorramabad, Lorestan province. The participants were selected according to the inclusion criteria using random sampling. Then, they were divided into case and control groups using a simple randomization method (45 ones in each group).

Inclusion and Exclusion Criteria

The inclusion criteria include informed consent to participate in the research, having a minimum level of literacy and understanding of the content sent through text messages, having a fixed personal mobile number to receive educational SMS, lack of any serious diabetic complication, and not having special diets because of specific diseases or physical problems limiting physical activity. Exclusion criteria include suffering from serious complications of diabetes during the study, suffering from diseases that limit physical activity or nutrition, and the patient's unwillingness to receive educational messages.

Questionnaires

Data collection tools in this study included a demographic information form, International Physical Activity Questionnaire (IPAQ), Self-Care Scale developed by Tubert, and Self-Efficacy Scale. Demographic information included: age, height, weight, gender, educational level, employment status, marital status, and type of treatment. The IPAQ with seven items measured the duration of physical activity in the last week in four categories: moderate physical activity, intense physical activity, walking, and sitting activities. According to the scoring protocol in this questionnaire, the intensity of physical activity based on the ratio of energy consumption in terms of metabolic equivalent of task (MET) in the last seven days is classified into three levels: low, medium, and high. It was proposed by the World Health Organization and the Centers for Disease Control and Prevention in 1998 to measure the physical activity of people aged 15 to 69 years and its validity and reliability have been confirmed in 12 countries worldwide, including Iran [20,21]. A self-care questionnaire was used in this study that included 15 items in the areas of diet compliance, physical activity, blood sugar monitoring, insulin injection or diabetes pill consumption, foot care, and smoking, which was translated and standardized by Hamdzadeh [22,23]. The self-efficacy questionnaire, which is one of the constructs of the standard Health Belief Model Questionnaire, validity and reliability of which have been confirmed [24].

Data collection

After presenting a letter of introduction from the Iran University of Medical Sciences and obtaining the necessary permits, the researcher referred to a diabetes clinic in Khorram Abad and selected 90 people from among 200 eligible people using random sampling. People who were willing to participate in the study and met the inclusion criteria were assigned to the case and control groups (45 in each group) using a simple randomization method. After random allocation, blood sugar samples were taken in all groups four days before the start of the intervention. In the first session, the researcher explained the purpose of the meeting to the participants and written informed consent was obtained. Then, the personal information form and questionnaires were completed by the case and control groups. The case group received an educational program in the form of short educational messages via mobile phone, for four weeks and on average, at least three to four messages per day related to the educational content, including exercise, self-monitoring of blood sugar, diet, insulin therapy, medication use, and foot care. For example, short messages about physical activity and blood sugar monitoring were "for people with diabetes, walking is the best exercise" or "it is better for people with diabetes to measure their fasting blood sugar after waking up". To improve self-efficacy, encouraging messages about adherence to self-care were used. Finally, after two months, the same questionnaires (demographic, physical activity, self-care, and self-efficacy scales) were distributed and completed by the participants, and the blood sugar levels of the two groups were measured again. During this period, the control group did not receive any educational intervention. However, to comply with the ethical principles, an educational CD containing self-care training was given to the control group after completing the research.

Statistical Analysis

The data of the two groups before and after the intervention were entered into SPSS version 24 software and analyzed using Wilcoxon, Mann-Whitney, Chi-square test, independent t-test, and paired t-test at a significant level of 0.05.

RESULTS

The participants' average age was 51.01 ± 0.967, and the average height and weight were 164.57 ± 1.031 and 75.69 ± 1.101, respectively.

Before the implementation of the educational program, the case and control groups were matched in terms of demographic variables, including age, height, weight, gender, education, employment status, marital status, and type of treatment, and no statistically significant difference was observed between the two groups (Table 1).

Table 1: Comparison of the absolute and relative frequency distribution of demographic variables in case and control groups

Variable		Case		Control		P value
		No.	%	No.	%	
Gender	Female	31	69	26	57/7	0.796
	Male	14	31	19	42/2	
Employment	Unemployed	5	11	2	4	0.686
	Housewife	26	58	24	53	
	Self-employed	9	20	9	20	
	Public	5	11	10	22	
Education	Illiterate	5	11	4	9	0.479
	Primary school	17	38	10	22	
	Secondary school	9	20	5	11	
	High school	4	9	11	24	
	High school diploma	4	9	10	22	
	Higher education	6	9	5	11	
Marital status	Single	2	4	1	2	0.800
	Divorced	1	2	0	0	
	Widow	9	20	5	11	
	Married	33	73	39	87	
Type of treatment	Insulin	21	47	21	47	0.920
	Oral medication	20	45	22	49	
	Diet	4	9	2	4	
	Exercise	0	0	0	0	

There is no statistically significant difference in terms of the average score of physical activity, self-care, self-efficacy, and blood sugar between the case and control groups before the intervention, while after the intervention, the average scores of these variables, except for physical activity (P=0.8), was significantly higher in the case group compared to the control group (P<0.001). In the control group, before and after the intervention, no significant difference was observed in the average scores of physical activity, self-care, self-efficacy, and blood sugar (P>0.05) (Table 2).

The blood sugar level in all patients with different treatment methods (insulin, oral medication, diet) in the case group reduced after the educational intervention compared to before intervention, except for the patients who only used exercise to control their blood sugar (Table 3).

Table 2: Comparison of the average scores of physical activity, self-care, self-efficacy, and blood sugar, before and after the intervention in case and control groups

Scale	Group	Case	Control	p-value
		Mean ± SD	Mean ± SD	
Physical activity	Before intervention	677.5±954.938	307.5±461.75	0.6
	After intervention	903.75±973.125	655±925.625	0.8
	p-value	0.8	0.4	_
Self-care	Before intervention	2.31±0.813	2.38±0.844	0.12
	After intervention	3.38±0.688	2±0.906	0<0001
	p-value	0<001	0.22	_
Self-efficacy	Before intervention	2.7±0.4	2.7±0.3	0.15
	After intervention	3.7±0.7	2.7±0.7	0<0001
	p-value	0<001	0.286	_
Blood sugar	Before intervention	180±80.5	185±51	0.8
	After intervention	170±87.5	180±70.5	0<001
	p-value	0.009	0.491	_

Table 3: Comparison of blood sugar scores before and after the educational intervention in the case group

Method of treatment	Blood sugar level before the intervention	Blood sugar level after the intervention	Level of change
Insulin	227.09	217.92	-9.17
Oral medicine	173.48	170.65	-2.83
Diet	181	180.44	-0.56
Exercise	194	194.5	0.5
Medium	193.89	190.88	-3.02

DISCUSSION

The present study was conducted aiming to determine the effect of the educational intervention based on mobile phone short messages on self-care in patients with type 2 diabetes referred to the diabetes clinic in Khorramabad. The research findings suggest that the educational intervention through mobile phone short messages improved self-care in the case group, which is consistent with findings by Abaza et al. and Agbede et al. on the effect of the intervention based on mobile phone short messages in the self-care of diabetic patients and the findings by Yari et al. and Rahnavard et al. concerning SMS-based and self-care education of diabetic patients [25-28]. Krishna et al. reported that technologies such as mobile phones and text messages, which are currently part of people's daily lives, have the potential to influence self-care and improve people's health [29]. The approach of health education through SMS to promote self-care in diabetic patients is more welcomed than traditional approaches that require reading pamphlets or attending lectures [25,30].

In this study, self-efficacy also there was a significant difference in the case group in terms of self-efficacy after the educational intervention. Katz and Nordwall and Peymani et al. also found that interventions based on mobile phone messages improve self-efficacy and self-care [31,32]. Similar studies regarding the self-care of diabetic patients also indicate a significant difference in the average score of self-efficacy and self-care in the case group compared to the control group after the educational intervention. These studies are consistent with our work in that increasing self-efficacy causes the adoption of self-care behaviors in diabetic patients

[33,34]. Self-efficacy is an important prerequisite for behavior change [35]. An individual with low self-efficacy is less likely to make an effort to perform a new health behavior or to change the behavior he is used to [36]. Researchers believe that self-efficacy has a suitable framework for understanding and predicting and patient's commitment to self-care behavior in the treatment of diabetes [37].

The results of the present study showed that education through mobile phone short messages does not affect increasing physical activity in the case group, which is in line with the findings by Bakhshian et al regarding the effect of education through mobile phone short messages on self-care of patients with type 2 diabetes [38]. It is also in agreement with the findings by Kim et al. on adherence to diabetes control recommendations [39], while our findings are not consistent with the study of Paul et al. regarding the use of software that can be installed on mobile phones to improve the amount of daily walking in patients with a history of stroke [40] and the study Martha et al. concerning mobile phone SMS intervention on diabetes self-care activities, cardiovascular disease risk awareness, and food choices among type 2 diabetic patients [41]. This discrepancy can be due to the lack of sports facilities and parks in the current study or the addition of chronic diseases to the patients participating in this research, as well as social and cultural factors that prevent people from doing physical activities in public environments. In the present study, since the number of women is more than men, the problem of social and cultural factors could be more marked.

The use of mobile phone messages in the current study showed a significant positive effect on the reduction of blood sugar in the case group after the educational intervention, which is consistent with the findings of similar studies in this field [42,43,44]. In patients suffering from diabetes, education is as valuable as medicine, exercise, and diet, because the treatment will never be effective unless the patient is well aware of the nature of his disease and takes positive steps to deal with it.

CONCLUSIONS

The results of this study demonstrated that educational interventions based on mobile phone short messages can be effective in enhancing self-care in patients with diabetes. Educational interventions aimed at empowering diabetic patients by strengthening self-care in them can be an effective way to improve the health of patients with diabetes. Therefore, it is recommended to use patient empowerment programs, especially with a self-care approach, to improve the health of patients.

Conflicts of interest and sources of funding

Abstract: *According to the results of the study, there were determined the peculiarities of military values of servicemen who participated in hostilities and had signs of PTSD and moral trauma. The study included 397 servicemen (aged 20 to 55 years) with combat experience. The study showed that PTSD and violation of moral normativity were closely related to unfavorable social conditions of performing combat tasks. Unlike PTSD, the moral normativity indicator was less tightly related to the immediate threat to life. The structure of values of the servicemen had no signs of PTSD as well as no violation of moral normativity consisted of factors that indicated the value of teamwork, responsibilities for decisions and actions made based on ideas related to loyalty to the oath and the Motherland, resistance, and professionalism. For the servicemen who participated in hostilities who had violations of moral normativity, it was more important to have the ability to act following their conscience, not to lose dignity, and to remain honest in the faces of their brothers than to have professionalism, loyalty to the oath and the Motherland.*

Keywords: *values, violation of moral normativity, serviceman, combat experience, post-traumatic stress disorder*

INTRODUCTION

The topic of the moral suffering of a serviceman who participated in hostilities had always been acquiring relevance when there occurred armed conflicts. However, after the Second World War [1], Wars in Vietnam [2], Korea [3], Iraq, and Afghanistan [4-5], etc. the topic of moral suffering was largely replaced by the study of psychiatric disorders of servicemen and, in particular, the disorders of combatants. However, the practice of providing psychiatric and psychological assistance showed that the approaches and activities proposed to overcome the symptoms of PTSD were ineffective to overcome the moral injury of the combatant. Thus, Gray, Schorr, Nash, and others [6], Griffin, Purcell, Burkman, and others [7], Maguen, Lucenko, Reger, and others [8] indicated that there was not any confirmed treatment for mental health disorders for today.

Thus, the construct of moral trauma was offered to describe the suffering that some veterans experienced while carrying out the actions during the fight that violated their belief in their kindness and benevolence of the world [9], and could undermine confidence in themselves, others and the world in general [10]. It gave the possibility to identify them as potentially traumatic experiences which differed from the traumas which were based on fear and were related to post-traumatic stress disorder. Thus, Bryan, Roberge, Leifker, and Rozek [11] found out that the servicemen, who faced a life-threatening injury and developed post-traumatic stress disorder, had the profile of symptoms that primarily included loss of memory, nightmares, memories, and exaggerated reaction concerning fright. Griffin et al. and Williamson et al. suggested that the profile of symptoms of those who underwent moral damages more often included a higher level of guilt, anger, shame, depression, and social isolation [12-13].

Frankfurt and Frazier believed that the study of moral damage had to occur in three directions: a) the definition, prevalence, and potential correlation of actions (e.g., military training, leadership, combat actions, and personality); b) the relationship between actions and syndrome of moral trauma (e.g., demoralization and self-injuring), and c) mechanisms of the genesis of moral trauma (e.g., shame, guilt, social isolation, and self-disposal) [9].

Joseph Wiinikka-Lydon pointed out that the nature of moral damage would be misunderstood if the determination of moral injury did not take into account the relationship which provoked the appearance of damage, so due to his words it was advisable to determine moral injury as the injury that occurred among people within moral ecology of wartime considering it to be a form of intersubjectivity [10].

Shay highlighted that the army could be considered a moral structure. The general expectations and values of the army formed the moral universe, which servicemen considered "legitimate", "natural" and "obligatory for themselves" [14]. Thus, the morality of the servicemen was tightly related to the military organization and depended on it, close to the fact that the army could make a serviceman ready to risk his/her own life. Due to the specific and strong moral connection between the serviceman and the army, according to Shay, its violation could have catastrophic consequences.

Williamson, Greenberg, and Murphy in their study determined that moral injury had negative consequences for psychological well-being. Among the examples of potentially morally injurious events (PMIE), which caused moral trauma and were described by British military veterans in the course of their study – bad treatment of civilians or hostile combatants, obtaining an order to violate the rules of combat, and disrespect for corpses [15].

It was quite clear that having such reasons, veterans did not readily resort to the discussion of the experience, which was often used in PTSD. Thus, Shay pointed out that civilians would rather prefer outspoken stories about injuries, as that could lead to doubts related to their moral beliefs and "could bring them back and disorient them" [14]. Although according to Shay, this attitude was understandable, as it came from the moral construction of a "normal human life" [14], he emphasized that it could interfere with treatment.

British researchers [15] found out that even discussing PMIE with friends, colleagues, or family members was considered catharsis; veterans did not report that it helped to solve their moral dissonance. Veterans did not consider social support to be a way to solve problems. The study by Williamson with colleagues showed that the solution of moral dissonance that arose in the sphere of value was described by veterans as a key turning point and led to a decrease in their emotional stress and improvement of daily functioning [15]. These researchers considered it quite promising to overcome the consequences of moral injury by finding ways to resolve the conflict between systems of values for example, military values against civilians), as well as conflicts within the system of values (for example, the conflict between military moral obligations such as respect for civilian life and combatants of opponents and respect for the value of colleagues’ protection and successful mission performance.

Overcoming a moral conflict that arose was also important because the moral conflict, which was associated with a particular event, could generate fundamental moral conflicts that went beyond this event [16].

Describing existing studies of the category "moral trauma", it was necessary to note that from the very beginning of its research, the talk was about moral conflict, conflict in the sphere of values, but they were preceded by the studies conducted at the beginning of 2000s related to the peculiarities of value orientations of servicemen who had signs of PTSD after deployment.

Thus, almost decades ago, German researchers Zimmermann, Firnkes, Kowalski, Backus, Siegel, Willmund, and Maercer, worried that empirical studies of the peculiarities of valuable orientations of servicemen who had post-traumatic disorder after their deployment were very limited in time; the factors which were related to the deployment provided ideal scientific conditions” [17]. The studies which were available at that time concerning post-traumatic symptoms and personal values were devoted to the victims of crimes and people with adaptation disorders after critical life circumstances [18].

However, having formulated the topic of the study devoted to the values of the servicemen who had post-traumatic stress disorders due to deployment-related servicemen P. Zimmermann, Firnkes, Kowalski, Backus, Siegel, Willmund, and Maercer focused on personal values and did not pay attention to specific military values.

Almost at the same time as there was formulated the problem of value orientations by servicemen with signs of PTSD, there occurred studies were based on the study of values of servicemen who survived traumatic events. The studies were related to the differentiation between post-traumatic stress disorder and moral injury [16].

It could be confidently said that the study of the sphere of values and mental traumatization of servicemen became one of the reasons for reviving interest in the topic of moral injury of servicemen.

METHOD

Participants and Procedure

The presented article research had a fairly simple plan with a minimum of used psychodiagnostic techniques and groups, which was caused by the peculiarities of its conduct. The study was conducted within the frames of the program of restoration of servicemen who participated in hostilities. The examination was carried out before the rehabilitation to determine the depth of traumatization and peculiarities of the state of servicemen. The study had a searching basis and was intended to formulate problems important for the development of effective programmers related to the prevention of psychological traumatization of combatants.

The study was conducted in 2022. The study included 397 servicemen of combatants. The studied group consisted of officers – 29.84% (from a junior lieutenant to a colonel) and contract servicemen and mobilized – 70.16% (from a private to a senior warrant officer). The age of the studied participants ranged from 20 to 55 years.

Using the results obtained according to the methods "Maladjustment" and "Mississippi Scale for Combat-Related PTSD", a sample of studied servicemen who participated in hostilities was divided into three groups: group 1 – servicemen who did not have signs of maladjustment and PTSR – 277 individuals; group 2 – servicemen who had signs of violation of moral normativity (5 or more points according to the scale of VMN and more than 15 points according to the total indicator of maladjustment) – 59 individuals; group 3 – servicemen who had signs of post-traumatic stress reactions (78 or more points according to the Mississippi Scale) – 61 individuals. It had to be noted that all the servicemen, without any exceptions, who had signs of VMN servicemen also had signs of PTSD (78 or more points according to the Mississippi Scale). The third group included the servicemen who had signs of PTSD but did not have the peculiarities of VMN and maladjustment in general which exceeded the norms. Unfortunately, available tools did not give the possibility to divide the participants into groups without being specified in the second group "crossroad".

All procedures carried out in the study conformed to the ethical standards of the 1964 Helsinki Declaration and its later amendments. All participants gave consent for their data to be used in this research.

Instruments and Measures

One of the reasons that there was a small number devoted to the studies of the "moral trauma" of servicemen was the lack of development of psychodiagnostic tools. In this study, as a criterion of moral trauma there was used a "violation of moral normativity" (VMN) – the scale of "maladjustment" techniques [19], which gave the possibility to differentiate individuals who had doubts about the expediency of using morals standards to regulate the relationships between individuals, as a result of which there was a loss of feeling of psychological well-being and signs of maladjustment arose.

The "maladjustment" technique was a rapid version of the "adaptability" technique [20], which had a long tradition of use in the Armed Forces of Ukraine. The "adaptability" technique was concluded by the Russian military psychologist Maklakov [20] to determine the adaptation potential of servicemen based on individual MMPI scales [21]. The developer reported the satisfactory psychometric characteristics of the concluded methodology. Since the beginning of hostilities in eastern Ukraine, the Maklakov methodology modification "Adaptability 200", formed by Chermyanin and Kondratiev, was widespread among military psychologists of Ukraine [22]. Unlike the previous methodology, it was supplemented by several issues that allowed us to distinguish "military-professional orientation", "tendency to deviant behaviors" and "suicidal risk" and to calculate "the level of resistance to combat stress". This technique consisted of 200 questions, so there was a need for a simpler and more reliable toolkit, which was the basis for the development of an express version of the methodology. The developed method of "maladjustment" [19] was aimed at the identification of specific and the most influential ability to adequately perform the tasks, and violations of adaptation potential. Thus, the technique had 4 scales, each with 10 issues – "violation of behavioral regulation", "probability of committing suicidal attempts", "violation of moral normativity", and "loss of communicative potential". There was the proposed calculation of the total indicator of "maladjustment". This calculation was simple and convenient and could be carried out in the field without any additional tools. Although the work with the technique involved the presence of trust in a psychologist, the technique had a scale of sincerity. The developers provided data on satisfactory psychometric indicators of the technique.

There was used the method "Mississippi Scale for Combat-Related PTSD" to determine the presence of post-traumatic stress reaction" [21]. At this time, it was one of the most common techniques used to measure PTSD symptoms of servicemen. The scale included 35 statements, each of which could be estimated under a five-point scale. The technique involved the process of distinguishing 3 levels – up to 77 points were normative indicators; 78-97 points were separate symptoms of PTSD; 98-145 points were the clinical variant of PTSD.

To determine the connection of violation of moral normativity with the action of combat stress factors, there was used the procedure of correlation analysis, and the method of "assessment of psychological trauma of combat experience of servicemen" by Doctor of Psychological Sciences Kolesnichenko [23] based on American methodology "Scales of assessment of combat experience" [24]. While developing the method there was taking into account the traumatic events and their intensity which was typical for the hostilities in Ukraine with the beginning of the Russian invasion in 2014. Unlike the "Scale of Evaluation of Combat Experience", this technique was a list of phenomena that reduced the trauma of the impact of combat stress factors. The technique had 5 scales that corresponded to 3 groups of combat stress factors and 2 factors that described internal and external resources to counteract stress factors. In the process of standardizing the technique, there was used regression analysis procedure, which gave the possibility to determine the contribution of each scale to acute stress disorder due to the action of combat stress factors. It was reported that the technique had satisfactory psychometric characteristics.

To determine the military values there was used a purposefully developed questionnaire.

At the end of 2021, there was developed a "questionnaire of determining the military values of servicemen of the National Guard of Ukraine" based on ideas related to the military values that existed in the armed formations of Ukraine, ethical codes of servicemen of European countries [25-26], historical information about the Cossack Ethical Code of the Warrior, availability of law enforcement and combat functions in the professional activity of NGU servicemen, a new experience of participating in the hybrid war and counteracting the numerically predominant opponent [27]. The questionnaire included a list of 11 generalized values including their content. The serviceman needed to evaluate the importance of values from this list using a scale in which 0 was the least important and necessary value for military service, and 10 was the most important and necessary value for military service. The scores had to be repeated.

In the proposed list for evaluation, there were generalized military values that united some values that described the experience of performing service and combat activity by servicemen:

1. To be physically brave – capable of controlling their fear, showing courage in situations that involved risks, injuries, and death; to be ready to give life for their Motherland as well as for their sworn brother.

2. To be morally brave – to find the strength to act correctly, and fairly, not to be indifferent to the injustice, grief, and sufferings of those whom they, being law enforcement, must protect; be human, humane, to be an example for imitation.

3. To be disciplined – to be guided by the legal requirements of the commander and the statutes; the execution of the commander's orders was the basis for the confidence of each member of the unit that would not be supplied, they would perform a part of their work accurately and in time, it was the basis for the coherence of the unit's actions, the basis for effective interaction with other units, and the basis for the unification of forces to achieve a common result.

4. To be self-disciplined – to perform their work without reminders, to meet high standards of professionalism and morality, so that their sworn brothers could trust them and rely on them, know that they would not fail, would not betray, and would not disappoint; to make the right choice and to be able to control their fear.

5. To be honest – one that could be trusted by fellow people; did not hide their shortcomings from sworn brothers, but corrected them, constantly professionally improving and developing. If necessary, they could be able to ask and receive help from their sworn brothers to get rid of defects, shortcomings in personal development, and vocational training. To report the conflicts of interest, about changes in their physical or mental state, so that the commander and sworn brothers could take this into account while performing the task, they had to know to what extent they could rely on the servicemen. Not to perform or hide the illegal and immoral actions of the sworn brothers, as it could potentially be the basis for blackmail, distrust, and a sense of guilt and, as a consequence, it could destroy the team, jeopardize the lives of other brothers and fail the accomplishment of the task.

6. To be worthy – to meet moral and professional requirements as well as to meet the standards of the profession. To follow their conscience and to follow the principles of Cossack chivalry. To improve constantly and professionally, and to acquire the necessary knowledge and skills required for the profession. To remain open to new professional experiences, not to dwell in their self-development, and to be self-critical.

7. To be a team member – to be able to rely on a sworn brother, to trust in a friend on weapons; be the one whom sworn brothers could rely on (competent, honest, faithful, disciplined, and predictable for a friend); respect sworn brothers and the commander, clearly obey the orders, as they were the basis for the unit control, the basis for concentrating the forces of the whole unit on the task and adjusting the forces of different units; to use humor to support and stimulate the development of sworn brothers, not to humiliate them; to prevent discrimination of comrades on weapons by nationality, race, and gender, etc.; to be an example and assistant for recruits. Being loyal to their unit did not mean

that they had to cover the illegal or immoral actions of the sworn brothers, as such actions made them and their unit open for manipulations and blackmail from the side of enemies. Their actions did not have to throw a shadow at their unit as well as at their sworn brothers. To be guided by the principle – "sworn brothers took the first place, then went the task (mission), and only after – their interests." Remember that military affairs were teamwork; it was effective when everyone did their part of the work completed.

8. To be faithful – to be faithful to the military oath – not to betray members of their unit; not to participate in any actions that could harm their weapons, not to provide any information related to the countries that were disloyal to Ukraine, not to express judgments that could devour the honor and dignity of the Ukrainian Army (National Guard), to harm its reputation; to be faithful to the Ukrainian people – to be faithful to the principles of independence, democracy, and protection of the rights and freedoms of the people of Ukraine; to be faithful to the traditions of the Ukrainian people, to imitate the traditions of Ukrainian Cossacks; to protect Ukraine and the way of life of the Ukrainians, to serve the interests of the Ukrainian people; to be faithful to themselves – not to betray themselves, their principles, to be reliable, integral, and predictable for sworn brothers (as a basis for effective interaction)

9. To be resistant – not to give up to the enemy, as long as there was strength and opportunities to resist themselves or as long as there was strength and opportunities to resist at least one of their companions on weapons; not to accept mercy from the enemy. Bravely face all the difficulties of service (not to complain, not to spread the information concerning household difficulties, and workload, as it could be used as a way of manipulation by opposing forces and of undermining the image of military service).

10. To be free – to take responsibility for their actions, to be capable of self-thinking and decision-making, to assert and maintain their point of view, to realize their values and principles, not to be manipulated, blackmailed, etc.

11. To be professional – to perform tasks at a high professional level, to constantly acquire and improve professional knowledge, skills, and possession of personal weapons; to maintain a physical form at a level that did not interfere with the tasks; to maintain their awareness of modern weapons, tactics, including those used by the enemy; to acquire and share professional experience with brothers, to be susceptible to the professional experience of others.

In 2022 there was published a study, which presented the peculiarities of the values of servicemen with different military-professional statuses [27].

Data Analysis

There was conducted the comparison of values in the studied groups using the Student's T-criterion. To determine the structure of the sphere of values there was used the procedure of factor analysis by Principal Components. The statistical analysis was performed using the SPSS 22 statistical package.

RESULTS

At the first stage of the study, it was necessary to consider the way how correlated psychological traumatization, the indicators of VMN (maladjustment), and PTSD with the factors of psychological traumatization of servicemen. The results of this stage of the study were presented in Table 1.

Table 1: Relationship between maladjustment and PTSD with the indicators according to the methodology "Evaluation of Psychological Traumatism of Combat Experience of Servicemen who participated in hostilities".

Scales	**Unfavorable social conditions for performing combat tasks**	**Specific combat conditions which become traumatic**	**The unfavorable social situation of participation in hostilities**	**Internal resources of resistance – professional and psychological training**	**External resources – friendship, respect**	**General indicator, traumatization of experience**
«Maladjustment»						
Violation of behavioral regulation	0.55***	0.29***	0.26***	-0.15**	-0.17**	0.40***
Likelihood of committing suicidal attempts	0.44***	0.13*	0.20***	-0.20***	-0.21***	0.41***
Violation of moral normativity	0.39***	0.16**	0.23***	-0.09	0.00	0.37***
Loss of communication potential	0.32***	0.14*	0.19***	-0.09	-0.27***	0.36***
General indicator of maladjustment	0.50***	0.22***	0.27***	-0.16**	-0.20***	0.42***

*Note: *p≤ .05; **p≤ .01; ***p≤ .001*

As it could be seen from the proposed data, PTSD as well as violation of moral norms was the most closely related to "Unfavorable social conditions of performing combat tasks", such as the attitude of the population on the territories where there were the hostilities, media coverage of events, etc. However, unlike PTSD, VMN was weakly related to the direct threat to life – the number of shelling, bombings, encirclements, etc., which was described by the second scale of the methodology "Evaluation of Psychological Traumatism of Combat Experience of Servicemen who Participated in Hostilities" (r= 0.16, p≤ .01). Moreover, it was possible to highlight the data related to the relationship between the indicator of violation of moral norms (VMN) and the external resource that protected against traumatization – friendship, respect, attitude to the relatives – r=0.00. To some extent, they agreed with the presented data from a semi-structured interview with British researchers, who determined that social support was not crucial while overcoming moral trauma [15]. However, the relationship between the indicators of PTSD and "External resource", which was defined in this methodology as the support of family and friends, being statistically significant (r=-0.26; p≤ .001), was weak in terms of its density.

As could be seen, the VMN indicator was related to combat stress factors and factors that mitigated their impact, as well as moral trauma according to the existing descriptions of this psychological category. Therefore, it was considered to be possible to use the VMN indicator as one of the indicators of the presence of moral trauma in a serviceman, taking into account that currently there was practically no psychodiagnostic toolkit for its determination.

The next stage of the study was a comparison of military values and average ranks in selected research groups. These results were presented in Table 2.

As could be seen from the provided above data, the hierarchies of military values were quite similar in all three groups. The leading place in them was occupied by courage, and the least important was "Will" and "Resistance". However, each group had its characteristics.

Such peculiarities of the first group included the absence of expressed peaks and depreciations in the hierarchy – the gap between the largest ("Moral courage" (6.09±3.09)) and the smallest ("Will" (3.50±3.29)) indicators in the hierarchy of military values was minimal in comparison with others in the groups Moreover, in this group the indicators of courage ("Moral courage" (6.09±3.09), "Physical courage" (5.77±2.99)) and "Dignity" (4.68±2.89) had the lowest indicators among the compared groups (the latest feature also had the lowest rank in the hierarchy in comparison with other groups), and the indicators of "Professionalism" (5.03±3.47) and "Loyalty" (5.73±3.13) were the highest (the latest feature also had the highest ranks in the hierarchy of values in comparison with other groups). It was described in detail in comparison with other research groups.

Table 2: Indicators of military values among servicemen who participated in hostilities and had signs of VMN, PTSD, and those who did not have any disorders which occurred under the influence of combat stress factors

Military value	Studied individuals						The significance of difficulties		
	group 1		group 2		group 3		t_{1-2}	t_{1-3}	t_{2-3}
	without any disorders		with signs of VMN		with signs of PTSD				
	average	rank	average	rank	average	rank			
Physical courage	5.77±2.99	2	6.06±3.19	2	6.41±2.63	2	0.62	1.660	0.66
Moral courage	6.09±3.09	1	7.39±2.59	1	6.52±2.91	1	3.37**	1.03	1.730
Discipline	5.03±3.11	6.5	4.56±3.48	8	5.30±3.07	6	0.96	0.62	1.23

*Note: 0p≤ .1; *p≤ .05; **p≤ .01*

In the second group, such military value as "Moral Courage" (7.39±2.59) was emphasized and significantly elevated above the others. According to this indicator, servicemen of this group differed from the first group at a statistically significant level (t1-2=3.37, p≤ .01) and at the trend level from the group with signs of PTSD (t2-3=1.73, p≤ .1). Other most important values of servicemen with signs of VMN included "Physical courage" (6.06±3.19), "Teamwork" (5.83±2.71), and "Honesty" (5.67±3.07). In this group, there was no expressed depreciation of any values (average scores did not fall below 4). However, in contrast to other groups, the lowest scores, which occupied the last 11th position in the hierarchy of values, in this group belonged to such military value as "Professionalism" (4.22±3.17). The peculiarities of this group included significantly lower "Loyalty" indicators than in the first group (4.67±2.06; t1-2=3.25, p≤ .01) and slightly higher indicators of "Will" than in the other compared groups (4.33±3.51; t1-2=1.66, p≤ .1 and t2-3=1.96, p≤ .05), which only in this group did not occupy the last position in the hierarchy of values.

Comparing the ranks of servicemen who had signs of VMN (group 2) and servicemen who did not have signs of maladjustment and PTSD (group 1), the following information had to be noted: servicemen of group 2 had significantly higher ranks of "Dignity" (5 vs. 9). However, these ranks were lower than those of servicemen with signs of PTSD (group 3) and significantly lower ranks of "Loyalty" (7 vs. 3) and "Professionalism" (11 vs. 6.5).

Forming a general ethical portrait of this group, it was necessary to point out that for servicemen who had VMN, the ability to act following conscience, not to lose dignity, and to remain honest in the faces of their fellow men was more important than abstract ideas about professionalism, and loyalty to the oath and the Motherland. The typical peculiarity of this group was a higher level of personal responsibility for their actions, and reluctance to shift them on the actions posed by the orders or by the irresistible circumstances.

Although among servicemen with signs of PTSD (group 3), courage, as in other compared groups, occupied the highest position in the hierarchy of military values; however, in this group the indicators of "Physical courage" (6.41±2.63) were slightly higher than in the others. Thus, the differences with the group without any signs of VMN and PTSD occupied the level of the tendency to statistical significance – t1-3=1.66, p ≤ 0.1. Moreover, in this group, the differences between "Moral Courage" (6.52±2.91) and "Physical courage" (6.41±2.63) were minimal, which suggested that there was no expressed differentiation of these concepts in this group. Among the three most important military values of representatives of this group, in addition to "Moral" and "Physical courage", was "Dignity" (6.19±3.22). Such a high position of this value (rank 3) and significantly higher average values (t1-3=3.37, p ≤ .01 and t2-3=2.65, p ≤ .05) were a defining (significant) peculiarity of this group. Moreover, in this group, in comparison with all other groups, the indicators of "Will" were the lowest (3.15±3.07), according to which they differed at a statistically significant level from the group with signs of VMN – t2-3=1.96, p ≤ .05.

Comparing the ranks, it had to be pointed out that this group, in addition to the already indicated position of "Dignity", which differed from other groups, had a lower rank of "Loyalty" than in group 1 (8 against 3) and higher rank of "Professionalism" than in group 2 (7 against 11).

Thus, for the ethical portrait of group 3, it was typical not to allow oneself to be suspected of cowardice, they demonstrated courage that was not significantly guided by ideals – the protection of the Motherland or loyalty to the oath – but which was guided by the fear of not meeting the expectations of others, the fear of being accused of cowardice; for them, it was extremely important not to lose a sense of their dignity (respect of others and self-respect).

Perhaps the fact that servicemen without signs of maladjustment and PTSD were characterized by a lower level of "Courage" and "Dignity" and a greater orientation to "Professionalism" and "Loyalty" made their behavior more flexible and less dangerous – they were not so dependent on patterns of behavior, did not aspire to "heroism" and conflict, they focused on professional actions and loyalty to the oath and to the Motherland, which did not only reduce their victimhood but also made them more adequate concerning combat situations.

To clarify the obtained results, Table 3 there was presented the data of the factor analysis (with the procedure of simplifying the factor structure) for a better understanding of the structure of the sphere of values of servicemen who did not have signs of maladjustment and PTSD.

This factorial structure described 90.58% of dispersion peculiarities.

The first factor had a share of 21.91%. In other factors, the share was approximately the same and varied from 17.44 to 16.82%. The content of the first factor was determined by such variables as "teamwork" (0.819) and "loyalty" (0.794). This factor was marked as the conscious value of teamwork, belonging to the team, and brotherhood. The share of this factor reaffirmed that servicemen were aware of the importance and value of teamwork, and were aware of their strength as a group formation.

Table 3: The structure of military values of servicemen who did not have signs of maladjustment and PTSD

Variables	Factors				
	1	2	3	4	5
Dignity	-0.027	-0.010	-0.079	-0.080	0.984
Teamwork	0.819	-0.140	0.272	0.179	0.087
Loyalty	0.794	0.307	-0.130	-0.174	-0.141
Resistance	0.085	0.113	0.961	0.045	-0.083
Will	0.072	0.957	0.114	0.070	-0.006
Professionalism	0.010	0.065	0.046	0.977	-0.081

The second factor (17.44%) was closely linked to the variable "will" (0.957). It was interesting, that the content of this factor specified the variable "loyalty" (0.307). This factor was interpreted as their responsibility for the decisions made and actions taken based on their own beliefs about loyalty (oath, home, brothers, etc.).

The content of the third factor, the share of which was 17.26%, was correlated with the variable "resistance" (0.961). Some clarification of the content was made by the variable "teamwork" (0.272). This factor was marked as an awareness of the importance to keep up (being resistant) so as not to let their sworn brothers down.

The fourth factor (17.16%) was almost entirely determined by the variable "professionalism" (0.977), the reverse pole of this factor indicated the variable "loyalty" (-0.174). This factor was marked as the ability to act in the interests of the case, despite personal affection.

The fifth factor (16.82%) correlated with the variable "dignity" (0.984), such variables as "loyalty", "resistance", "will", and "professionalism" had weak feedback with this factor. This factor was marked as the ability to consciously comply with the given standards and standards of the profession and morality, which implied the ability to develop them, openness to the new, and the ability to self-criticism – "the ability to meet the changing situation". The presence of this factor in the structure of military values gave the possibility to be appropriate to changes that occurred during crucial events such as war.

There was developed a four-factorial structure of military values of servicemen with signs of VMN and PTSR (see Table 4).

Table 4: The structure of military values of servicemen who had signs of violation of moral normativity

Variables	Factors			
	1	2	3	4
Physical courage	-0.021	-0.100	-0.095	0.916
Discipline	0.915	-0.074	-0.007	0.030
Self-discipline	0.876	0.008	0.095	-0.271
Honesty	-0.210	0.870	0.138	0.101
Dignity	0.084	0.860	-0.162	-0.324
Loyalty	-0.713	0.078	0.043	-0.446
Resistance	-0.369	-0.386	-0.727	0.110
Will	-0.143	-0.178	0.927	-0.049

The factorial structure presented in Table 4 described 83.96% of dispersion peculiarities. The first factor had the highest share – 29.02%. Its content was determined by the direct connection between the values of "discipline" (0.915) and "self-discipline" (0.876). The reverse pole of the factor determined the value of "loyalty" (-0.713). The inverse relationship with “resistance” (-0.369) clarified the content of the factor. This factor was marked as the ability to comply with the requirement or internal conditions. This factor was not connected with beliefs or with endurance. The talk was mostly about the "habit" to be reliable for others to perform the assigned tasks, but not about the actions committed following abstract ideals – love for the Motherland, and loyalty to the oath.

The second factor (21.24%) was determined by the variables "honesty" (0.870) and "dignity" (0.860). Its content was clarified with the peculiarity "resistance" (-0,386). Unlike the fifth factor in the structure of servicemen who did not have signs of maladjustment and PTSD, this factor indicated not the correspondence of the current situation, but the correspondence of the existing relationships to the desire to meet the concept of decency in relations. It was the idea to preserve someone’s decency in the relationship that regulated their activity.

The positive pole of the third factor (18.17%) was almost entirely determined by the variable "will" (0.927), which described the importance of their responsibility for the decisions which were made as well as for the committed actions. The negative pole of the factor, like the first two, was associated with "resistance", but the third factor was much denser (-0.727). It was likely that servicemen, with the violated moral normativity, were aware that the maintenance of discipline and decent behavior as well as taking on full responsibility for their decisions and actions reduced their ability to be resistant which led to moral suffering.

The content of the fourth factor (15.53%) was interesting, which indicated that "physical courage" (0.916) was achieved by representatives of this group at the expense (resource of inverse relationship) of such values as "loyalty" (-0.446), "dignity” (-0.324), and “self-discipline” (0.271). Showing physical courage on the battlefield, these servicemen tried to maintain a previously created image of themselves, as decent, reliable people they used to consider themselves. It was possible that namely these resourceful connections could lead to exhaustion and moral crisis – a war that required brave actions, "squeezed" a drop of their usual ideas about themselves as reliable and decent people.

The structure of military values of servicemen who had signs of PTSD were given in Table 5.

Table 5: The structure of military values of servicemen who had signs of post-traumatic stressful reactions

Variables	Factors			
	1	2	3	4
Physical courage	0.782	-0.205	0.242	-0.090
Moral courage	0.887	-0.210	-0.046	0.028
Discipline	0.194	-0.196	0.194	-0.697
Self-discipline	-0.246	-0.268	0.772	0.055
Dignity	-0.763	-0.304	0.075	-0.091
Teamwork	0.255	-0.225	0.109	0.806
Honesty	-0.357	-0.032	-0.804	0.155
Resistance	-0.192	0.815	-0.066	0.173
Professionalism	0.067	0.810	-0.141	-0.179

DISCUSSION

The analysis of the results gave the possibility to describe servicemen who did not have signs of maladjustment and PTSR, as they were able to meet the difficult situation of participation in hostilities. These servicemen were not guided by the distorted ideas of courage and did not try to prove to anyone that they were not cowards, but instead, they acted being guided by their ideas related to professionalism and loyalty to the oath and the Motherland, due to that they were less victimized and more appropriate to the combat situations. Probably, such characteristics of the sphere of values of these servicemen could be reflected at the personal level of view of the army as a unique "moral structure" described by Shay [14], which gave it a possibility to be integrated into servicemen not only to maintain mental health but also to sacrifice their lives. These data confirmed previously made conclusions concerning the importance of relevant secondary socialization (professionalization) of servicemen, as prevention of their psychological traumatization under combat conditions [28] (p. 125).

Unlike the servicemen who were integrated into the moral construction of the army, combatants with signs of VMN had less abstract ideas about loyalty and become hostages to their image of a decent person, which could be counted by their sworn brothers. They were aware that keeping this image under the conditions of the war was the path of suffering and consciously they followed it. Every manifestation of physical courage for these servicemen became a step that took them away from themselves – from the ideas of their honesty and humanity. And despite this, they did not try to transfer responsibility for the actions taken into insurmountable circumstances and did not try to justify themselves with the need to act by order. These data expanded the idea of moral conflict, as the basis for moral trauma, described by Williamson with colleagues [15].

The obtained results also demonstrated that for servicemen with signs of VMN, as one of the manifestations of moral injury, social support was not a resource capable of solving their problems. These data agreed with the British researchers who determined that social support was not crucial in overcoming moral injury [15]. Moreover, the existing data showed that the construct of "moral injury" was more related to the social context of the situation, than the immediate threat to life.

The obtained results in the group of servicemen with signs of PTSD were quite interesting. Their traumatization, as expected, was related not only to the social context of participation in hostilities but also to the immediate threat to life. However, it was an unexpected assumption of the greater number of victims of these servicemen in comparison with those who had no signs of maladjustment and PTSD. It could be assumed that these servicemen could be hostage to their ideas about the need to manifest courage during hostilities, it was extremely important for them that others did not suspect them of cowardice.

For these servicemen, participation in hostilities was a life on the verge of their ideas about their capabilities, it was a test. It could be assumed that they had "excessive" expectations from their participation in hostilities, the requirements of the profession of a serviceman, which contributed to their exaggerated response to the situation of participation in hostilities (greater courage, aggressiveness, suspicion, etc.) and, accordingly, to the higher level of exhaustion. And although the assumption of "excessive expectations" as a peculiarity of their greater victimization was only an assumption related to the possible mechanism of formation of psychological traumatization of a military serviceman who participated in hostilities, its formulation, and further testing were important for the development of effective PTSD prevention programs.

Nowadays it was quite traditional to study the changes in the relationship under the influence of PTSD, but mainly they are related to the civilian life of veterans. Thus, in particular, Caska-Wallace, Smith, Renshaw, and Allen investigated the impact of PTSD on the marital relations of servicemen [29], Ellon, Colvonen, Haller, Norman, and Angkaw determined that the severity of PTSD was the only significant sign. The topic of the relationship between servicemen and the peculiarities of PTSD in the military team and with the commander was less studied. Moreover, these and other studies did not determine the role of values as regulators of relationships that were changed as a result of the psychological traumatization of servicemen.

Harper, Stanley, Exline, Pargament, Fletcher, and Teng found out that betrayal perception was positively linked to post-traumatic stress disorder. They suggested that the mechanism of communication of a potentially morally injurious event (PMIE) and symptoms of post-traumatic stress disorder was social separation (“promiscuity” from Russian). The mentioned researchers emphasized that the study of this mechanism was extremely limited. In the secondary analysis, they were able to distinguish that the interaction between betrayal and perceived social support (another significant issue and family) gave the possibility to predict the symptoms of post-traumatic stress disorder [31]. In the conducted research it was found that such values as "loyalty" of servicemen with signs of post-traumatic stressful reactions had the opposite position in the hierarchy of military values in comparison with the servicemen who had no signs of PTSD. And although the format of the study did not give the possibility to conclude whether the "loyalty" factor contributed to the development of PTSD or, conversely, the acquisition of signs of post-traumatic stress reactions led to the depreciation of "loyalty", it was also possible to assume that "social disconnection" was an important mechanism for the development of PTSD symptoms and there was a need in further study of the role of value regulation in the implementation of this mechanism.

Nowadays there were widespread studies that demonstrated that the cohesion of the military team was connected with a lower level of severity of post-traumatic stress disorder [32]. The conducted research gave the possibility to formulate another problem of the research – psychologically injured servicemen could reduce the coordination of the military team and the coordination of its actions.

The given data demonstrated that the PTSD indicator had a statistically significant, but the not very dense connection with social support as an external overcoming resource. These and other results of the study gave the possibility to suggest that more promising for determination of the ways of prevention of psychological traumatization of servicemen was not the study of social cohesion of military teams, but the study of the peculiarities of professional socialization of servicemen in which the cohesion of the military team was a derivative characteristic. In light of this, it was quite possible to assume that the study of the content and process of internalization of military values, as a means of professional socialization of servicemen, and their acquisition of professional identity, could expand the idea of ways of preventing psychological traumatization of servicemen who participated in hostilities.

CONCLUSIONS

The conducted study demonstrated that PTSD and VMN indicators were most closely related to adverse social conditions available for combat task performance. Unlike PTSD, VMN was less densely related to a direct threat to life. Social support had no preventive effect on VMN. The connection of a factor that described social support with PTSD was weak but statistically significant.

The servicemen who participated in hostilities and had no signs of PTSD and VMN had a slightly lower level of indicators of the value “bravery” in comparison with other studied groups, while they had a higher level of “professionalism” than in other groups of the study. Their structure of values consisted of the factors that testified to the value of teamwork; responsibilities for decisions and actions made based on ideas related to loyalty to the oath and the Motherland; resistance; professionalism as the ability to act in the interests of the case, despite personal affection; and the ability to be appropriate to the changing conditions. Such peculiarities made their pain integrated into the "moral construction of the army" and more appropriate (adaptive) to the combat situations, where dominated teamwork and professionalism as opposed to unjustified risks and excessive reflection.

For the servicemen who participated in hostilities and had VMN, it was more important to have the ability to act consciously, not to lose dignity, and to remain honest in the faces of their sworn brothers than to have professionalism and loyalty to the oath and the Motherland. The typical peculiarity of this group was a higher level of personal responsibility for their actions, an aversive to transfer it to the actions by the order or too insurmountable circumstances. In the structure of their values, the leading place was occupied by the factors that described the ability to comply with the standards; to remain honest in front of their sworn brothers; to be quite responsible for their actions. These factors in the group of servicemen who had VMNs were related to the realization that they made them vulnerable in combat. The process of following them led to suffering. The need to manifest physical courage (as the ability to be aggressive against another person) "squeezed" a drop of their usual ideas about themselves as reliable and decent people.

The "excessive" courage of servicemen who had signs of PTSD was a consequence not only of the desire to be guided by the ideals – the protection of the Motherland or faithfulness to oath, etc. – but the consequence of the fear not to meet the expectations of others, the desire not to lose their sense of dignity (respect of others and self-esteem). In the structure of their values, a leading place was occupied with courage and professionalism. Both of these factors in the group of servicemen who had the symptoms of PTSD involved the attitude toward them as if they required actions on the verge of their capabilities. Other factors in the structure of their military values indicated that they had a sense of unity with their team – leadership of their ideas concerning the relevance of actions, which made them less controlled and unreliable for brothers-in-arms as well as commanders under the combat conditions.

The presented study was mainly directed to theoretical research, and its main results were the formulation of research problems that were important for the development of an effective program for the prevention of psychological traumatization of servicemen who participated in hostilities. Unfortunately, the used format of the study did not give the possibility to state whether the peculiarities of the sphere of values made servicemen sensitive to the action of combat stress factors and to the specific reaction concerning them in the form of PTSD or VMN (moral injury), or vice versa, changes in the sphere of values were the results of the formation of signs of PTSD and VMN by servicemen who participated in hostilities. Moreover, there was a need for further research to clarify the role of military values in the mechanism of PTSD and VMN formation. Similarly, it was required to study and verify the suggestion related to the greater number of victims of servicemen who, participating in hostilities, acquired signs of psychological traumatization (maladjustment and PTSD). It was also advisable to study the impact of the peculiarity of secondary (professional) socialization of servicemen and their acquisition of military-professional identity as a factor in the prevention of psychological traumatization of a serviceman under combat conditions.

Abstract: *This study aimed to determine if: 1) C-reactive protein (CRP) level correlated with PTSD symptom severity as measured by PTSD Checklist-5 (PCL-5), and 2) ketone supplement reduced PTSD symptoms. Twenty participants with PTSD were randomly assigned to a ketone supplementation or placebo group and evaluated for 6-weeks for PTSD symptom severity and CRP levels. The Spearman Rank correlation between PCL-5 and CRP was positive, but not statistically significant. Mixed models on the ranks of the data were used to examine the difference in PCL-5 and CRP between ketone and control groups over time. Median PCL-5 at the pre-test was higher than at the post-test in the ketone group but not in the control. The reduction of PCL-5 medians between ketone and control groups at the post-test was not different. The median pre-test CRP was not different from than post-test in the ketone group or control group. This pilot study did not find a correlation between CRP levels and PTSD symptom severity but was limited by a lack of CRP data collection due to the loss of follow-up. PTSD symptom severity was not altered by 6 weeks of chronic ketone salt supplementation compared to the control group but should be examined in a larger sample size for further verification.*

Keywords: *PTSD; inflammation; PTSD Checklist-5; ketone salts; anxiety*

INTRODUCTION

Posttraumatic stress disorder (PTSD) is a severe mental illness that can develop after an individual is exposed to a traumatic event. Traumatic events which can trigger PTSD include, but are not limited to, exposure to combat, sexual violence, interpersonal violence, and accidental violent death. The lifetime prevalence of PTSD ranges from 7-8% in the United States [1].

PTSD is associated with recurrent, involuntary, and intrusive memories and nightmares of the traumatic event. Individuals often feel that the traumatic event is recurring, which can be triggered by exposure to stimuli that evoke memories of the event. These symptoms are incredibly distressing and can promote avoidance of situations that involve triggers, potentially leading to impairment in daily activities [2]. PTSD is also associated with significant cognitive and mood dysfunction [3]. Furthermore, patients suffering from PTSD have higher rates of both psychiatric and physical comorbid disorders than the general population. Psychiatric comorbidities include substance use disorder, anxiety disorders, and depressive disorders [4]. Physical comorbidities found in veterans include greater incidences of cardiovascular, musculoskeletal, metabolic, and neurological diseases [5].

While the symptoms and morbidity associated with PTSD are well-documented, treatment continues to present a challenge, due to the lack of clear understanding of the pathophysiology of the disorder, and the barriers to access to treatments that have been proven to be effective. Current treatment guidelines vary, but generally recommend psychotherapy as a first-line therapy [6,7], with the addition of SSRIs or SNRIs if refractory, although some suggest that SSRIs should be part of initial therapy [8-12]. Prazosin has also been shown to be effective in reducing symptoms of PTSD, especially in individuals with elevated blood pressure [13]. However, all of these treatments have considerable drawbacks and barriers. Psychotherapy of any kind is time-consuming and often expensive, and many patients with PTSD do not have access to the consistent care necessary for improvement; even with improved access to care, many people do not utilize resources available due to internal factors, such as lack of motivation or fear of embarrassment due to stigma associated with the disorder and mental health in general [14]. SSRIs and SNRIs have a wide range of side effects, including weight gain and sexual dysfunction, and are sometimes discontinued for these reasons [15]. Additionally, because individuals with PTSD are at higher risk of comorbidities such as diabetes and obesity, these side effects are especially unfavorable. For these reasons, a nutritional supplement that could reduce the symptoms of PTSD in affected individuals would be of considerable value in reducing the burden of the disorder in many individuals.

Past research has shown that there are higher levels of pro-inflammatory cytokines in combat-exposed males with PTSD than in combat-exposed males without PTSD, suggesting that inflammation may play a role in PTSD symptomatology [16, 17]. Another study found that higher levels of C-reactive protein (CRP) were associated with increased PTSD symptom severity in African American women with Type 2 diabetes mellitus [18]. Several other studies have found that PTSD is correlated with higher levels of CRP, but the populations only included African Americans and veterans, respectively [19,20]. For the results to be generalizable, studies that identify the relationship of CRP (and inflammation) with a mixed demographic diagnosed with PTSD are needed.

Ketones are molecules naturally produced by the liver during limited carbohydrate availability that act as both a fuel source and signaling molecule. They are widely available as commercial supplements and are used for a variety of purposes. Ketones possess physiologic properties such as anti-inflammatory actions that may provide benefits for PTSD symptoms. Beta-hydroxybutyrate, a ketone, has been shown to inhibit NLRP3 inflammasome activity in human monocytes, displaying the potential anti-inflammatory effects of ketogenic diets/supplements [21]. In a case report, a ketogenic diet was shown to treat Crohn's disease and significantly reduce levels of CRP [22]. In addition, current evidence suggests that ketogenic diet therapies can be therapeutic in treating epilepsy, nonmotor Parkinson's disease, cognition and cerebral blood flow in Alzheimer's patients, and Type 2 diabetes [23]. However, there are no studies that investigate the effect of ketone supplementation on CRP levels in PTSD patients. Therefore, the questions posed by this preliminary report are:

(1) Do high levels of CRP—as an inflammatory blood marker—correlate with PTSD symptom severity (measured by PTSD Check List – 5 questionnaires)? We hypothesize that CRP levels positively correlate with PTSD symptom severity.

(2) Is there a difference between the level of CRP in blood in the group of participants receiving adjunct ketone supplements versus placebo? We hypothesize that patients on a ketone supplement have lower CRP levels compared to those on a placebo.

MATERIALS AND METHODS

Experimental Design

In this randomized, double-blinded, placebo-controlled clinical trial, participants were assigned to one of two groups—an experimental group receiving an adjunct ketone supplement to their usual treatment (or no treatment) and a control group receiving an adjunct placebo. The duration of the trial was 6 weeks, with either the ketone or placebo supplementation consumed twice daily. Phone calls, adherence logs, and text messages were used to monitor compliance with the regimen. Participants visited the laboratory for a familiarization visit which included an explanation of the study, proper completion of the informed consent, and collection of demographic and medical history information. Participants were also advised to fast for 10 hours (only water was allowed) and withhold from exercise, caffeine, and nicotine for 12 hours before the following data collection visits. Following familiarization, participants visited the laboratory twice for data collection: once at baseline and then again at the end of the 6-week intervention. The study was approved by the University's Institutional Review Board, and all procedures performed complied with the institutional guidelines. This study was registered as a clinical trial (ClinicalTrials.gov Identifier: NCT04083352) and a CONSORT 2010 Flow Diagram is provided in Figure 1.

Participants

A total of 20 participants were recruited. Participants were recruited via the Veteran Success department, paper flyers on the University's campus and in the local community, a local news interview, the Mood and Trauma Outpatient Clinical Program, Veteran organizational meetings, and the local Warrior Project. The study inclusion criteria were: (1) a diagnosis of PTSD and (2) men and non-pregnant women from 18-65 years old. No exclusion of PTSD patients who were taking medication for psychiatric comorbidities. Exclusion criteria were pregnancy, chronic smoking, and/or taking cardiovascular-related medications 12 hours before and during evaluations. Patients who were taking prescribed medication continued doing so at the same dosage throughout the trial.

♦ Excluded from analysis (n=0)

Measures

To determine PTSD symptom severity, the PTSD checklist (PCL-5) was completed by each participant at the beginning and the end of the trial with an interviewer present for questions or clarification. C-Reactive Protein (CRP) was also measured for each participant at both the beginning and end of the trial. To measure CRP, venous blood samples were collected by an investigator and immediately transported to the Clinical Pathology Laboratory at the University's Hospital for subsequent analyses. The CRP analysis was performed on an automated chemistry analyzer (ADVIA 1800 Chemistry System; Siemens Healthineers, Erlangen, Germany).

Supplement

Participants were randomized to consume a ketone salt supplement or a placebo in conjunction with their normal diet and medication regimen. The ketone salt and placebo supplements were in powder form. The participants were instructed to take two packets a day mixed with water, once in the morning and once in the afternoon, for 6 weeks. The ketone salt supplement included 7 g of beta-hydroxybutyrate combined with erythritol, L-Taurine, fermented L-Leucine, citric acid, natural flavor, vegetable juice color, stevia, xanthan gum, beta carotene and approximately 920 mg of sodium (KETO//OS® MAX, Prüvit Ventures, Inc., Melissa, TX). The placebo supplement included maltodextrin and similar color, sodium, and flavoring, as the ketone salt supplement. Both supplements contained 41 kcal per serving.

Statistical Methods

All statistical analysis was performed using SAS 9.4 and statistical significance was assessed using an alpha level of 0.05. Due to the small sample size, rank-based and exact methods were used for all analyses. Descriptive statistics were determined by the ketone group and included frequencies and percentages for categorical variables and medians and interquartile ranges for continuous variables.

Fisher's Exact tests for categorical variables and Wilcoxon rank sum tests for continuous variables were used to examine differences by ketone groups for baseline values. Spearman Rank correlations between PCL-5 and CRP at baseline were determined.

Mixed models using the ranks of the data using the minimum variance quadratic unbiased estimation of covariance parameters method of estimation and assuming an unstructured covariance structure were used to examine changes over time between ketone groups for PCL-5 and CRP.

The denominator degrees of freedom were calculated using the Kenward-Roger method for factors in the model that did not involve time, and for factors that did involve time the denominator degrees of freedom were infinity. Each model included fixed effects of the ketone group and time as well as the two-factor interaction.

The F-test for the two-factor interaction was the statistical test of interest and the statistical significance of this F-test was determined using the Brunner, Domhof, and Langer (2002) method [24].

A Bonferroni adjustment to the overall alpha level was used to examine post hoc pairwise differences.

RESULTS

Table 1 gives the descriptive statistics by ketone status and the results for examining differences in baseline values. Briefly, 27% of those in the ketone group and 11% in the control group were male. The average age in the ketone group was 44 yrs and 50 yrs in the control group. There were no statistically significant differences between the ketone and control groups for gender, age, PCL-5, or CRP. The Spearman Rank correlation between PCL-5 and CRP was positive, but weak with a value of 0.21 (n=12, p=0.5149), and was not statistically different from zero.

Table 1: The descriptive statistics by ketone status and the results for examining differences in baseline values are shown in this table. *Abbreviations: CRP, c-reactive protein; n, number; PCL-5, PTSD Checklist 5; Q, quartile; SD, standard deviation*

Variable	Ketone N=11 (55%)	Control N=9 (45%)	P-value
Male Gender – n (%)	3 (27.3)	1 (11.1)	0.5913
Age – mean (SD)	44.8 (9.1)	40.0 (12.7)	0.3017
Baseline			
PCL-5 – median (Q1-Q3), n	58.5 (38.0-67.0) N=10	34.0 (26.0-60.0) N=9	0.1207

	Control	Pre	0.47	0.09-1.62		
		Post	0.27	0.09-0.46		

The results examining differences in PCL-5 or CRP over time between groups on the ranks of the data are given in Table 2.

The interaction between ketone and time was not statistically significant for PCL-5 indicating that the changes over time in the median PCL-5 scores in the ketone and control groups were not different.

The median PCL-5 at the pre-test was statistically, but not clinically, significantly higher than at the post-test (p=0.0003) in the ketone group but not in the control group (p=0.4418). There were no statistically significant differences in the PCL-5 medians between the ketone and control groups at the pre-test (p=1.0000) or post-test (p=0.6020). The interaction between ketone and time was not statistically significant for CRP indicating that the changes over time in the median PCL-5 scores in the ketone and control groups were not different. The median CRP at the pre-test was not significantly different from than post-test (p=1.0000) in the ketone group nor in the control group (p=1.0000). There were no statistically significant differences in CRP between the ketone and control groups at the pre-test (p=1.0000) or post-test (p=1.0000).

DISCUSSION

In this study, we did not find a statistically significant or clinically meaningful correlation between CRP levels and PTSD symptom severity. In addition, there was no significant difference in baseline CRP levels in patients in the ketone supplement group compared to the placebo group.

Several studies have examined the relationship between inflammation and PTSD. Lindqvist et al. examined the relationship between pro-inflammatory cytokines and PTSD in combat-exposed males. The study included 51 participants with PTSD and 51 participants without PTSD, comparing their "pro-inflammatory score", which consisted of summed standardized scores of Interleukin 1 beta (IL-1β), Interleukin 6 (IL-6), Tumor Necrosis Factor-alpha (TNFα), Interferon-gamma (IFNγ), and CRP. PTSD symptom severity was measured using the Clinician-Administered PTSD Scale (CAPS). The study found that subjects with PTSD had significantly higher pro-inflammatory scores compared to those without PTSD, with a p-value of 0.002 after controlling for early life trauma, depression diagnosis and severity, ethnicity, asthma/allergies, body mass index, education, possible confounding medications, and time since combat exposure. However, within the PTSD group, the pro-inflammatory scores were not significantly correlated with CAPS total score [16].

Lindqvist et al. conducted a replication study with a different cohort (31 combat-exposed participants with PTSD and 30 combat-exposed participants without PTSD). Again, they found that those with PTSD had higher total pro-inflammatory scores compared to those without PTSD. In addition, there was no significant correlation between pro-inflammatory score and PTSD symptom severity [17].

More recently, a study by Powers et al. examined the relationship between inflammation and PTSD. The study consisted of 55 traumatized African American women with type 2 diabetes mellitus. Participants were selected from a publicly funded hospital in Atlanta, Georgia, drawing from a low socioeconomic, urban minority population. The Clinician-Administered PTSD Scale (CAPS) was used to measure PTSD symptom severity, and CRP levels were taken as a measure of inflammation. The study found that CRP levels were positively correlated with PTSD symptom severity (p<0.01) [18].

Our study results indicated that CRP levels were not correlated with PTSD symptom severity. However, there are several differences to note. First, we measured PTSD symptom severity with PCL-5 rather than CAPS, which was the assessment used in previous studies. In addition, our study had a very small sample size—only 7 participants had data on both baseline and follow-up CRP levels. Because of this, it is difficult to draw any meaningful conclusions regarding CRP from the results obtained from this study.

One finding of note was that there was a statistically significant difference between pre-test and post-test PCL-5 scores in the ketone group, but not in the control group. However, because the difference was small and the difference in pre-test mean scores was large, this finding is not clinically significant. However, it does indicate that ketone supplementation should be further studied as a method of symptom reduction for PTSD patients. Future studies should aim to have a larger sample size to hold more statistical power, as the small sample size was a limitation of this pilot study.

CONCLUSIONS

This pilot study did not demonstrate a correlation between CRP level and PTSD severity; a statistically significant nor clinically meaningful correlation was not found between CRP levels and PTSD symptom severity measured by the PCL-5. In addition, there were no differences in CRP levels between the ketone salt supplementation and placebo groups, which suggests that ketone salt supplementation may not alter the levels of this inflammatory marker in individuals diagnosed with PTSD. However, as mentioned in the discussion, the study was limited by small sample size and ketones as a method for symptom reduction in patients with PTSD merit follow-up with a larger scale study due to their potential to provide more accessible relief if they are proven to be effective.

Conflicts of interest and sources of funding

The authors declare no conflicts of interest. Angelia Holland-Winkler received funding for this project from Augusta University's College of Education and Human Development and Prüvit Ventures, Inc. Ketone and placebo supplements were provided by Prüvit Ventures, Inc.

Authors' contribution

Authors include Langston Gilmore, Nagy Youssef, Jennifer Waller, Rebecca Nalloor, Max Wieder, and Angelia Maleah Holland-Winkler (PI). AMH-W designed the research, AMH-W and RIN collected the data, JLW analyzed the data, LBG, NAY, JLW, RIN, MAW, and AMH-W drafted and edited the manuscript. All authors read and approved the final manuscript.

Ethics approval and consent to participate

This study was approved by Augusta University's Institutional Review Board with approval number 907405. All subjects signed an approved and stamped informed consent document before participating.

Patient consent for publication

Informed consent was obtained from all subjects involved in the study.

Abstract: *Introduction: Social responsibility and, is an indicator that is important in the epidemic of diseases with high prevalence and death rates. The current study aims at determining the relationship between social responsibility and COVID-19 in the population covered by health centers in Iran. Methods: 500 people participated in this descriptive-analytical study. The data was collected using a researcher-made social responsibility questionnaire in the context of the Covid-19 pandemic in three areas general, individual, and social responsibility. The quantitative content validity method was used to measure the validity of the questionnaire and Cronbach's alpha calculation method was used to measure its reliability. The data were analyzed using SPSS-21 software. Findings: Among the participants, 4.32% of them had a history of covid-19, and the history of complications was more in men (51.9%) and the mean social responsibility score of women was higher (P<0.001). The average responsibility score was higher in people without a history of Covid-19 than in people with a history of Covid-19 (P=0.006). Conclusion: Individuals with higher social responsibility observed more health protocols and had lower rates of covid-19 infection among them. Therefore, in the design of educational interventions, planning should be done to increase people's sense of social responsibility.*

Keywords: *social responsibility, health, COVID-19*

INTRODUCTION

The prevalence and incidence of various infectious diseases throughout history have been one of the most serious threats to human health; the most recent of which is the emerging COVID-19 virus from the coronavirus family [1]. COVID-19, which appeared in Johann, China in December 2019 [2] is considered a threat to the health and lives of millions of people worldwide [3]. This disease has changed the lifestyle of millions of people around the world [3], and in Iran, it is very prevalent, endangering the physical and mental health of people [4]. Individuals' responsibility for health is one of the most important aspects of a healthy lifestyle, with which a person chooses a lifestyle to maintain and promote his health and prevent diseases [5].

Since a human is a social being and lives in society from the moment of birth to the end of life and is in constant interaction with other human beings, he/she must always learn how to satisfy his/her life and needs in society. This requires learning social skills. One learns these skills within the socialization process, and if these skills are learned properly, it can lead to the formation of social responsibility [6].

According to Glaser, responsibility is formulated in the form of three components: first, learning to choose behaviors that meet our basic needs, second, accepting the consequences of our behavior, and third, it should not be an obstacle to meeting the needs of others [7]. Considering that social responsibility improves social abilities, academic motivation, attention to moral and social concepts, personal adaptation, sense of accountability to others, commitment to society, etc [8]. and given that responsibility is the outcome of three characteristics of recognition, decision, and creativity, so responsible individuals are conscientious, confident, serious, and possibly disciplined [6]. Besides, the goal of the health system is to promote the health of the community, and the factors that shape the behavior cause prevention and reduction of diseases and improvement of the community health, and the best platform and solution to achieve this goal are measures related to social responsibility [9]. Thus, considering previous research findings, and given the importance of the subject of social responsibility in the health of individuals, and since no study has been conducted on the relationship between social responsibility and COVID-19 in Iran, the present research was carried out for investigating the relationship between social responsibility and COVID-19 morbidity in the population covered by health centers of Iran in 2021.

MATERIALS AND METHODS

The present study is a cross-sectional research (descriptive-analytical) that was conducted on 500 individuals covered by Andimeshk city health centers in 2021. Andimeshk city is located in the north of Khuzestan province and southwest of Iran.

Inclusion criteria were having informed consent to participate in the study and literacy of completing the questionnaire, and exclusion criteria included the reluctance of the participant in each stage of the study and incomplete completion of the questionnaire.

The questionnaire used in this study is an author-made questionnaire on social responsibility during the COVID-19 pandemic. The designed questionnaire includes 13 demographic items and 32 items related to responsibility. With a review of related literature, two areas were considered including self-health responsibility for own health (individual area) and health responsibility for the health of others (social area).

Items of individual health responsibility area were designed according to the health responsibility dimension of the Health-Promoting Lifestyle Profile II (HPLP II) questionnaire established by Walker, which consisted of 12 items (items 1-12). The options are scored on a Likert scale ranging as strongly agree, agree, no opinion, disagree, and strongly disagree from 5 to 1, respectively. The range of scores in this area is between12-60. The items of the questionnaire related to the social responsibility area were designed according to the Social Responsibility Questionnaire developed by Harrison Goff, which included 20 items (items 13-32). To measure social responsibility in the social area, personality traits such as conscientiousness, sense of commitment, hardworking, seriousness, trustworthiness, discipline-based behavior, and behavior following the sense of responsibility towards family, society, and the world were considered. The items 19-20-25-27-28-29-30-31 were scored as strongly agree, agree, no opinion, disagree, and strongly disagree from 5 to 1, respectively. Items 16-17-18-21-22-23-24-26-32 were scored inversely, i.e., strongly agree, agree, no opinion, disagree, and strongly disagree from 1 to 5, respectively. Therefore, the range of scores in this area is between20-100. To assess the validity of the questionnaire, the quantitative content validity method was used by the panel of experts, and Cronbach's alpha calculation method was used to evaluate the reliability of the questionnaire, which was obtained as 0.78.

The sample size was calculated based on Cochran's sample size formula. To determine the sample size, by considering alpha as 0.05 accuracy as d = 0.4, and standard deviation as 6, the sample size was determined to be 484, which was increased to 500 for increasing the validity of the study, and 500 individuals completed the questionnaire as the research sample. Due to the problems related to the COVID-19 pandemic and the impossibility of face-to-face visits to collect information, the samples were selected using the convenience sampling method. So, to conduct the study, the questionnaire was initially developed The data were analyzed by SPSS software version 21. Mean and standard deviation as well as frequency distribution tables were used to describe the characteristics of the subjects. An Independent t-test was used for the comparison of responsibility scores in terms of the history of COVID-19 morbidity. To investigate the relationship between overall responsibility, as well as health responsibility for one's health (individual area) and health responsibility for the health of others (social area) with the chance of COVID-19 morbidity, Simple Logistic Regression was used at a significant level of 0.05. Then, the relationship between baseline characteristics variables and the chance of COVID-19 morbidity was measured at a significance level of 0.2. Variables that had a statistically significant relationship with the chance of COVID-19 morbidity were individually entered into the Multiple Logistic Regression model at a significance level of 0.2 to eliminate their confounding effect on the relationship between responsibility and history of COVID-19 morbidity. In case of the presence of variables with a confounding effect on the relationship between different areas of responsibility and the chance of COVID-19 morbidity (more than 10% change in the COVID-19 chance associated with responsibility), they are entered in the final model (simultaneously) at the significance level of 0.05. The variables of age and home space have entered the models as centering for interpretability of intercept of the regression model collected virtually through the questionnaire design website (https://porsline.ir/), and then the questionnaire link was sent to the participants through the largest virtual page of Andimeshk city news agency on Instagram. This page is mostly followed by residents of Andimeshk city, and it has about 70k members with a high rate of daily likes and visits. Following the completion of the questionnaire, it was available to us through the Porsline website.

RESULTS

Finally, 500 individuals were analyzed in this study, of which 162 (32.4%) had a history of COVID-19, and 338 (67.6%) did not report a history of COVID-19 morbidity. Of those with a history of COVID-19, 42 reported transmitting the disease to others.

Out of the total number of people surveyed, 321 (64.2%) reported that at least one of those around them had been infected by COVID-19 in the past. 210 (42%) were registered in the self-declaration system of the Ministry of Health (Table 1).

Table 1: Baseline characteristics of the participants in the study

Variable		No.	Percent
Incidence of COVID-19	No	338	67.6
	Yes	162	32.4
Gender	Male	240	48
	Female	260	52
Education	Illiterate	13	2.6
	Below high school degree	46	9.2
	High school diploma	95	19
	Higher education	346	69.2
Number of Household members	1	5	1
	2	50	10
	3	67	13.4
	Above 3	378	75.6
Proper ventilation of the residential house	No	124	24.8
	Yes	376	75.2
Registration in the COVID-19 self-declaration system	No	290	58
	Yes	210	42
Frequency of morbidity of COVID-19	No morbidity	340	68
	once	139	27.4
	Twice	19	3.8
	More than 2 times	4	0.8
Morbidity of COVID-19 in relatives	No	179	35.8
	Yes	321	64.2
Behavior leading to COVID-19	travel	4	2.5
	Going to a party	45	28
	Not wearing mask	38	23.6
	No hand sanitization	5	3.1
	Non-observance of social distance	18	11.2
	Contaminated work environment	35	21.7
	Caring for a patient with COVID-19	16	9.9
Transmitting your disease to others	No	379	75.8
	Yes	42	8.4
	I don’t know	79	15.8
Having underlying disease	No	56	11.2
	Yes	443	88.8

In the total subjects, the means of overall responsibility, responsibility in the individual area, and responsibility in the social area were equal to 126.17 ± 22.85, 44 ± 10.68, and 82.17 ± 14.77, respectively. In all areas, the mean score of responsibility of individuals with a history of COVID-19 was lower than those without a history of COVID-19, so that, the scores of overall responsibility, individual responsibility, and social responsibility in individuals with a history of COVID-19 were 5.93, 2.43, and 3.50 less than the scores of those without a history of COVID-19 (P <0.05) (Table 2).

Table 2: Comparison of the mean scores of different areas of responsibility in terms of the history of COVID-19 morbidity

Different areas	History of morbidity of COVID-19	No.	Mean ± SD	Difference of means	95% confidence interval		P-value*
					Lower limit	Upper limit	
Overall responsibility	Non-infected	338	128.09±22.23	5.93	1.67	10.20	0.008
	infected	162	122.15±23.67				
Individual responsibility	Non-infected	338	44.79±10.60	2.43	0.43	4.42	0.017
	infected	162	42.36±10.70				
Social responsibility	Non-infected	338	83.30±13.87	3.50	0.74	6.26	0.013
	infected	162	79.80±16.28				

** Independent Sample T Test*

As shown by the results of univariate analysis, for one unit increase in score of overall responsibility, individual responsibility, and social responsibility, the chances of morbidity of COVID-19 decreased by 2%, 3%, and 2%, respectively, which was statistically significant (P <0.05) (Table 3). There were statistically significant relationships between variables of literacy level, home space, history of COVID-19 in others, the transmission of COVID-19 to others, the presence of underlying disease, and age of individuals and the chance of morbidity of COVID-19 (P<0.20) (Table 3).

Table 3: Relationship between different areas of responsibility and baseline characteristics with the morbidity of COVID-19

Variable		OR (95% CI)	P-Value
Overall responsibility		0.98 (0.98, 0.99)	0.007
Individual responsibility		0.97 (0.96, 0.99)	0.018

** adjusted Odds Ratio for the relationship between responsibility and COVID-19 morbidity*

*** Percentage of OR change for relationship between responsibility and COVID-19 morbidity compared to its unadjusted state*

In the multiple logistic regression model, it was found that none of the variables of literacy level, home space, history of COVID-19 in others, the transmission of COVID-19 to others, presence of underlying disease, and age of individuals had a confounding effect on the relationship between overall responsibility, individuals responsibility, and social responsibility and morbidity of COVID-19 (Table 4).

DISCUSSION

The present study was conducted aiming at investigating the relationship between social responsibility and COVID-19 disease. A total of 500 residents of Andimeshk city in Khuzestan province in the southwest of Iran were surveyed.

The results of our study showed that individuals with a history of COVID-19 have lower scores of overall responsibility, individual responsibility, and social responsibility than those without a history of COVID-19 disease. Besides, the mean score of individuals' responsibilities for their health in the social area was higher than the individual area, and this finding is consistent with the study of Khajeh Nouri [8].

The mean score of responsibility in all areas surveyed was higher in individuals without a history of COVID-19 disease and those who showed better adherence to health protocols. In general, individual and social responsibility is a very important variable since it shows a person's commitment to his/her behavior, and the higher the commitment of individuals to an issue, its achievement would be easier realized through one's individual and social responsibility. Moreover, Thome maintains that social responsibility is based on a sense of commitment in individuals [10].

The results of the univariate analysis of our study showed that for one unit increase in score of overall responsibility, individual responsibility, or social responsibility, the chance of developing COVID-19 is decreased. The results of the present study also showed that men were more likely than women to get infected by COVID-19. This is in line with the findings of Brodin on the safety factors determining the manifestation and severity of COVID-19 disease. According to his results, he believes that men are more prone to COVID-19 disease than women [11]. Of course, the presence of men in crowded areas is a factor in increasing infection. Besides, men have poorer performance in terms of following health protocols than women [12], which increases the chances of getting the disease and this indicates less responsibility and commitment of men.

In this study, those registered in the COVID-19 self-declaration system of the Ministry of Health had a lower chance of getting infected by COVID-19, and this implies higher social commitment and responsibility of people to comply with health protocols and recognition of the infected cases and cutting the transmission chain. Because people are more committed to health, related behaviors are manifested in them earlier for anxiety management, and this suggests a responsibility to their health and those around them. It was also mentioned in the study of Fathi et al., and the author believes that individuals with higher responsibility experience less COVID-19 anxiety [13].

Our results demonstrated that for every year of age increase, the chances of getting infected by COVID-19 increase. The age variable itself is a determining factor in COVID-19 morbidity. This finding is in agreement with the findings of other studies [14-16].

In the present study, people who transmitted the disease to others had a higher chance of getting infected again because these people usually have a lower risk perception of the disease and also have lower health responsibility. This finding is consistent with the findings of Robinson's study [17].

In the present study, those with the underlying disease were more likely to develop COVID-19 disease, which is consistent with the study of Dadgari [14]. In our study, individuals with literacy levels below high school, high school, and higher education levels showed a lower chance of COVID-19 morbidity compared to those with an elementary school degree. They performed better following the health instructions and social responsibility, and this finding was in line with the study of Kharamin et al [12].

Usually, when people around you are not responsible, they create obstacles and problems for others that can increase their chances of risk. Our findings also indicated those with a history of COVID-19 morbidity among those around them are more prone to be infected, which this finding is consistent with the findings of Sahebi [7].

The results of this study demonstrated that in the case of COVID-19 morbidity, the most common causes of COVID-19 disease were related to behaviors, going to parties, not wearing a mask, and the contaminant work environment, respectively. Moreover, the chance of COVID-19 morbidity was less in less populated households and families with larger homes and more well-ventilated houses.

Consequently, given that the average score of social responsibility is higher in individuals without a history of COVID-19 disease and with better adherence to health protocols, research findings indicate that the more individuals take responsibility, the more attention they pay to the consequences of their actions, take their action and issues more seriously and try harder to solve them [18].

CONCLUSIONS

According to the results obtained in different studies, further research can be done to deepen the existing knowledge in the field of the correlation between social responsibility and health and different diseases and COVID-19 morbidity. In general, the component of responsibility should be institutionalized at different levels of society from the younger ages with different strategies, so that it can play an effective role in human health and the prevention of events and diseases.

Conflicts of interest and sources of funding

The personal interests of the authors were not related to the results of this research. The authors declare that they have no competing interests. This study did not receive any grant from funding agencies.

Acknowledgment

This article is a part of the approved draft of the master's thesis in health education and health promotion with code 99-3-74-19532. In this way, the authors highly appreciate all those who helped us in the process of conducting our research.

Authors' contribution

All authors were responsible for the study. EA, MM, and TD were accountable for the study Conceptualization and led the writing of the paper. BI conducted the Literature review and assisted in writing the paper. MM and OS performed the Statistical analysis, assisted in interpreting the data, and wrote the paper. OS, FSI, and EA assisted with the interpretation of the results and drafting of programmatic Implications. FB and MM were responsible for data collection and coordination of the study. TD co-led the conceptualization, supervised all aspects of writing the paper, and provided extensive comments on the manuscript. All the authors have read and approved the final manuscript.

Ethics approval and consent to participate

This study was approved by the Research Ethics Committee, Iran University of Medical Sciences with the code IR.IUMS.REC.1399.1199. Informed consent was obtained from all individual participants included in the study before conducting.

Patient consent for publication

All participants consented verbally to the publication of the interview data.

Abstract: *Different factors may be involved in the clinical heterogeneity of spinal muscular atrophy disease. The vitamin D receptor (VDR) might be a candidate gene for this disease. Our study aimed to assess the preferential transmission of VDR polymorphisms from parents to SMA children. We genotyped 261 subjects (87 SMA nuclear families) for VDR FokI, BsmI, ApaI, and TaqI polymorphisms. The transmission of the genetic marker was estimated with Plink and FBAT software. It detected a preferential transmission of the rs731236 and rs7975232 variants to SMA1 patients and of rs1544410 variants to SMA2 patients. The variants of rs2228570 were preferentially transmitted to parents of all SMA patients. Haplotype analysis identified that haplotypes C-C-G-A and T-A-A-G seem to be involved in the booth type of SMA whereas the impact of T-A-A-A seems to be limited only to SMA2. Strong linkage disequilibrium (LD) between rs7975232 and rs1544410 was detected in samples from parents. Even though we investigated a small number of nuclear families the results suggest a potential link between VDR polymorphisms and SMA disease.*

Keywords: *SMA, TDT analysis, VDR gene*

INTRODUCTION

Spinal muscular atrophy (SMA) refers to a group of hereditary recessive neuromuscular diseases leading to muscle weakness and infant mortality. The clinical onset of spinal muscular atrophy 1 (SMA1 or Werdnig Hoffmann disease) is evident in the first 6 months of life whereas for spinal muscular atrophy type II (SMA2 or Dubowitz disease) it is observed at ages 6 - 12 months.

The main symptoms of SMA1 and SMA2 are degeneration of anterior spinal cord motoneurons, muscular hypotonia, or atrophy. They are determined by mutations (e.g. homozygous deletion, punctiform mutations, or complex rearrangements) in the SMN1 locus (5q13.2) [1,2] but are influenced by other factors (e.g., mutations in SMN2, NAIP, PLS3) [3,4,5].

Vitamin D is involved in mineral metabolism and interferes with immune response, apoptotic and anti-proliferative processes, or neuromuscular function [6,7,8,9]. Vitamin D deficiency may predispose to reversible muscle weakness, wasting, and instability of gait [10,11], whereas supplementation with this vitamin may increase muscle strength in athletes [12] and reduce the risk of cancer death [13].

The vitamin D receptor (VDR), encoded by the VDR gene (12q.13.1), is a nuclear receptor belonging to class 2 of the family of steroid receptors. Several VDR polymorphisms (e.g. VDR FokI, BsmI, Apa, TaqI) have been associated or in linkage with different human diseases (e.g. diabetes mellitus type 1, osteoporosis, allergic diseases), including carcinomas and neurological disease (e.g. Parkinson's disease, Alzheimer's disease, multiple sclerosis, SMA1) [14,15,16,17,18,19]. However, the association between VDR polymorphisms and neurological diseases remains a subject of debate.

This study aimed to investigate the transmission of VDR polymorphisms in nuclear families with SMA1 or SMA2 patients.

MATERIALS AND METHODS

Subjects

For families with SMA type, 1 (n=43) or type 2 (n=44) patients who were referred to several hospitals from Bucharest (Romania), 24 of them were also included in a previous publication [19]. Diagnosis of SMA was based on age at clinical onset and of homozygous deletion of SMN1 exon 7. SMA1 patients never achieve sitting whereas those with SMA2 could sit but were not able to walk, according to classification criteria [20,21].

Genotyping

DNA was isolated using a commercial kit (The Wizard® Genomic DNA Purification Kit) from peripheral blood (0.5 ml) collected on EDTA anticoagulant tubes. The homozygous deletions of SMN1 exon 7 or 8 were tested by PCR -RFLP and the homozygous deletion of NAIP exon 5 was tested by PCR and electrophoresis, according to the previously published protocols [22,23,24]. VDR polymorphisms Taq (rs731236), Apa (rs7975232), Bsm (rs1544410), and Fok (rs2228570) were genotyped using PCR-RFLP method, as was previously described [19,25,26]. Restriction products were resolved in electrophoresis. The genotype of each sample was established independently by two investigators.

Statistical analysis

The frequencies of alleles and haplotypes, linkage disequilibrium (LD) between markers, and the pattern of genetic markers transmission from parents to affected offspring (Transmission disequilibrium test – TDT) was performed with Plink [27] and the FBAT (Family Based Association Test) software [28]. The linkage between VDR markers in samples from parents and the LD plot was estimated with Haploview 4.1 [29]. A p-value of 0.05 was considered statistically significant.

RESULTS

The gender distribution was similar in SMA1 and SMA2 patients (51.16% and 52.27%, respectively were boys).

The parents of children with SMA1 (25.76±3.42; 19-36 years old) or SMA2 (25.86±3.55; 19-35 years old) had similar ages. The age of patients with SMA1 was significantly lower than that of SMA2 (8.39±4.21 months vs. 13.33±3.54 months, $p < 0.0001$). The genetic test showed that all investigated parents have at least one copy of the SMN1 gene. The homozygous deletion of SMN1 exon 8 or NAIP exon 5 was detected more frequently in patients with SMA1 than in those with SMA2 (53.48% vs. 40.91%; and 25.58% vs. 20.45% of cases).

The distribution of all VDR genotypes in the sublot of parents and rs1544410 in the sublot of SMA patients are not in agreement with Hardy Weinberg's principle (Table 1). Only the Minor Allele Frequency (MAF) of rs1544410 is in the interval of values reported in 1000 Genomes for VDR polymorphisms (Table 2) [30].

The results obtained with FBAT and Plink software reveal a preferential transmission of the VDR alleles from parents to SMA children. The calculated statistical significance was much stronger for rs731236 and rs7975232 and more reduced for rs1544410 and rs2228570. These results depend on the type of disease; it was detected a preferential transmission of the rs731236 and rs7975232 variants to SMA1 patients and of rs1544410 variants to SMA2 patients (Table 3, Table 4).

Table 1: The distribution of VDR polymorphisms in sublots of SMA patients and parents

			SMA1	34	14	2.43; 0.004
			SMA2	37	24	1.54; >0.05
rs1544410	A	G	All	48	75	0.64; 0.02
			SMA1	23	31	0.74; >0.05
			SMA2	25	42	0.6; 0.04
rs2228570	G	A	All	42	69	0.61; 0.01
			SMA1	17	30	0.56; >0.05
			SMA2	24	39	0.62; >0.05

Note: The results of the TDT test performed for families with SMA cases (plink)

The frequency of haplotypes in SMA families was estimated with FBAT software (Table 5). The most frequent three (rs731236-rs7975232-rs1544410-rs2228570) haplotypes estimated for SMA1 and SMA2 families were C-C-G-A (0.120 vs. 0.147), T-A-G-A (0.116 vs. 0.145), T-A-A-G (0.115 vs. 0.124) and, the rarest was C-A-G-A (0.009 vs. 0.003). Statistically significant results were identified between C-C-G-A and both types of SMA, T-A-A-G haplotypes, and SMA1 disease and between T-A-A-A and SMA2 (Table 5).

We found a strong linkage disequilibrium (LD) measure between rs7975232 and rs1544410 and a less significant linkage between rs7975232 and rs731236 (Figure 1).

Table 5: VDR haplotype analysis in SMA families (FBAT software)

Haplotypes	Families	Frequency of haplotype	fam#	S-E(S)	Var(S)	Z;P
C-C-G-A	SMA All	0.133	36	12.589	10.339	3.91; 0.00009
	SMA 1	0.120	12	6.082	4.166	2.98; 0.003
	SMA2	0.147	21	7.464	6.647	2.89; 0.004

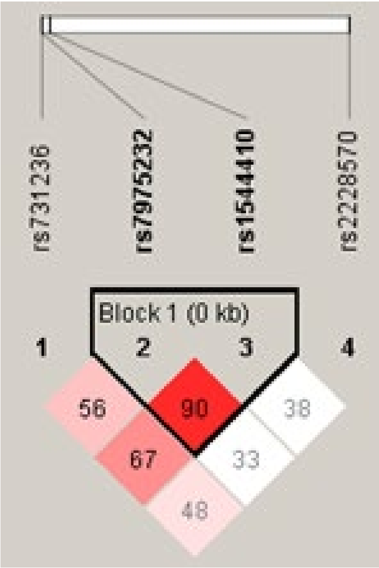
Figure 1: VDR LD plot estimated for the four polymorphisms identified in samples from parents



DISCUSSION

We performed a family-based association test, to bring new data regarding the relationship between VDR gene polymorphisms and SMA disease [19]. The transmission disequilibrium test, unlike the case-control association study, is not susceptible to population stratification. Eighty-seven families with children diagnosed with SMA1 or SMA2 were included in this study. The observed distribution of mutations may reflect some characteristics of families included in this study. Thus, the homozygous deletion of SMN1 exon 8 (53.48% and 40.91% respectively) in blood samples from our SMA1 and SMA2 patients was less frequent than in other populations (100% and 91.48%). These differences may be explained by the results of Vijzelaar R. and colleagues who considered that the distribution of SMN mutations is influenced by population background [31].

The homozygous deletion of NAIP exon 5 in SMA1 and SMA2 patients (25.58% and 20,45% respectively) was in the range of values reported in other studies (9.5%-82.85% respectively) [32,33,34].

The distribution of VDR polymorphisms in the sublot of parents is not in agreement with Hardy Weinberg equilibrium. In addition, the distribution of rs731236, rs1544410, and rs2228570 in a subgroup of parents differs from those reported in public databases [35]. However, the MAF values for rs2228570 estimated in this study and previous research performed in the population from South Romania are similar (0.378 vs 0.365) [36]. In this sublot of subjects, we also detected much stronger linkage disequilibrium (LD) between rs7975232 and rs1544410 than between rs7975232 and rs731236. This result is not following data from public databases [30]. These results could be explained, at least partially, by the size of this sublot of subjects and by the criteria used for selection.

In families investigated in this study, the C-C-G-A and T-A-A-G haplotypes were linked with booth types of SMA whereas T-A-A-A could be in relation only with SMA2 (Table 5). In a previous case-control study, we found an association between SMA1 and VDR haplotypes C-C-G-A (OR= 2.8, p=0.02) or T-A-A-A (OR= 0.27, p=0.03) [19].

The rs1544410, rs7975232, and rs731236, located near the 3'end of the VDR gene, were supposed to be non-functional. We detected a preferential transmission of the rs731236 and rs7975232 variants to SMA1 patients, and rs1544410 variants to SMA2 patients. These markers may be in linkage disequilibrium with a potential functional VDR polymorphism.

The rs2228570 was mapped in exon 2 of the VDR gene, in a potential translation initiation start site. Its variants were associated with two receptor variants: a long version of the protein (the T variant) and a shortened variant by three amino acids (the C variant). The VDR C variants seem to interact more efficiently with transcription factor TFIIB [37]. The variants of rs2228570 were preferentially transmitted to parents of all

SMA patients (Table 5).

This is the first report of a TDT test performed for VDR gene polymorphisms in SMA diseases. The results indicated that some VDR polymorphisms may be preferentially transmitted from parents to SMA patients. This result is completing the literature reports about the preferential transmission of VDR gene polymorphisms alleles in various diseases like diabetes [38, 39], rheumatoid arthritis [40], tuberculosis [41], or bone mineral density [42].

In conclusion, our data indicated a potential transmission of VDR variants from patients to SMA1 or SMA2 patients.

Conflicts of interest and sources of funding

The personal interests of the authors were not related to the results of this research. The authors declare that they have no competing interests. This study did not receive any grant from funding agencies.

Abstract: *The evolution of society, the development of the Internet, and the increased need for medical services generated the emergence of telemedicine. The visual and auditory connection between the doctor and the patient allowed good communication, but the limitation of the clinical examination remained a problem. Tele-echography complements tele-consults and brings valuable information in many specialties. Our study is conducted on data obtained by organizing the first network of telemedicine with tele-echography in the country. The ultrasound examinations targeted only the abdomen, but the structure also allows tele-echocardiography as well as the extension to other services at distance. The purpose of the study is to objectively assess the ability of tele-echography to complete the teleconsultation with information on which we can rely. The national tele-echography network was created by distributing 40 tele-echographs in the country, one in each county, in the family doctors' offices. The obtained data were analyzed statistically. The study shows that tele-echography can be performed with very good accuracy in synchronous mode but low in asynchronous mode, which required re-examination or resumption of examination in the reference medical center. The widespread use of tele-echography associated with teleconsultations can have favorable consequences on the medical act, the quality of life of the patients and the doctors, and society by reducing pollution and urban agglomerations.*

Keywords: *tele-echography; teleconsultation; abdominal echography*

INTRODUCTION

Telemedicine is defined as a technique that comprises the usage of information and communication technologies (ICT) to enhance the access of patients to distant healthcare providers and technologies [1].

Tele-echography or tele-ultrasonography (Tele US) uses remote transmission to provide enhanced US diagnosis, based on the opinion of remote experts. TELUS is frequently performed at the point-of-care (PoC) by primary care doctors, with a profound impact on patients located at remote destinations [2].

The aim of the organization of the national network telemedicine with tele-echography is to provide patient-centered care, with enhancement in the clinical decision-making for individual cases. The procedures' results are amplified by the involvement of specialists as remote experts [3].

The results of previous studies have motivated the organization of the first tele-echography network in Romania [4,5,6].

In the studies carried out in the field of telemedicine with tele-echography, the following disadvantages are identified: the deficit of specialized medical staff, the difficulties of time management, and the costs of equipment and the internet [7,8,9].

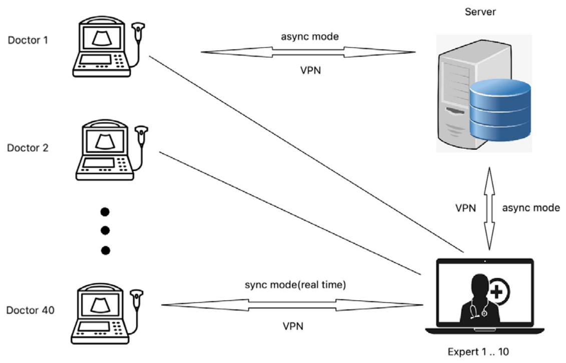
The national telemedicine network with tele-echography is made up of 40 tele-echography centers organized as follows: In each county, the Lotus Image medical center from Targu Mures provided a tele-echography through which tele-consultations, including tele-echography, were performed with the specialists.

In this preliminary retrospective study, we present the details of this structure and the statistical analysis of the accumulated data from abdominal examinations. The presented data demonstrate the increase in the quality of the medical service when tele-echography is associated with teleconsultation and motivates the extension to the other specialties: cardiology, obstetrics and gynecology, pediatrics, endocrinology, and senology.

MATERIALS AND METHODS

The components of the tele-echography network are a doctor, portable POCUS device -Telemed LS64 FLT-1T with EchoWave II (EWII) software, a virtual private network (VPN)-secure, private, and encrypted online connection, remote expert. The two main parts of the process are the transmission and reception of ultrasound images. The transmission is done by the ultrasound device and the internet connection. The reception is made up of personal computers or smartphones with dedicated soft. In asynchronous mode, the third component intervenes, the server where echography films are stored and downloaded later by experts. In synchronous mode, the examinations are made at the same time and the result of the examination is issued immediately after its completion.

Figure 1: Tele-echography network



Synchronous examination or real-time is the most appreciated method of examination by patients, examining physicians, and experts because it alleviates the possibility of timely interaction between the three of them, the adjustment by verbal guidance of the examination to obtain the correct images and their interpretation in the clinical context and release the results immediately after the end of the examination.

Asynchronous examination or store-and-forward has the advantage that the videos and results are saved digitally and can constitute both an image database and forensic documentation in case of malpractice process. The second advantage is that it allows greater flexibility in the working time for the patient-examining physician and expert but is subject to the risk of incomplete or incorrect results with the possible consequence of requesting the resumption of the examination from the expert.

The national tele-echography network that was created within this project had both options. As a result, through the activity in the network, a database was established consisting of both the storage of echography videos and of the standardized results.

By entering the standardized elements in an excel database, a complex statistical analysis was possible, which included the following elements: the reasons for the patients' presentation for tele-echography, the number of organs completely or incorrectly reviewed, the ability to visualize the spleen and kidney, the collaboration with the patient to obtain and maintaining apnea necessary for a correct examination of the upper abdomen.

RESULTS

The study group resulted from the selection of approximately 3000 tele-echography abdominal examinations performed in synchronous and asynchronous modes within the created network. The results of the examinations were drafted and standardized, and the parameters were entered into the excel database. Incomplete results and re-examinations were excluded. The created database contains both medical documents and video recordings. The distributions of the ”reasons for presentation” for the tele-echography examination are shown in Table 1, Figure 2. A large proportion of persons presented themselves to the specialist for screening (30.3%). This parameter illustrates the awareness of the population for prevention and confirms the role of this method to meet the needs of the patients. Chronic abdominal pain syndrome and nonspecific syndromes were the reasons for teleconsultation with tele-echography in another third of the patients.

Figure 2: Reasons for the presentation at the tele-echography

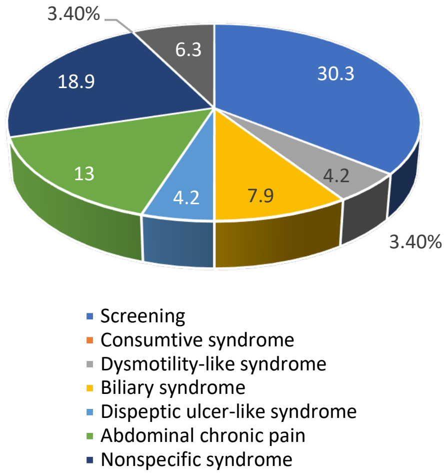


Table 1: The reasons for the presentation at the ultrasound

Reasons for the presentation	Number	Percentage
Screening	144	30.3
Consumptive Syndrome[1]	16	3.4
Dysmolity-Like Syndrome[2]	20	4.2
Biliary Syndrome[3]	38	7.9
Dyspeptic Ulcer-Like Syndrome[4]	60	12.6
Abdominal Pain Syndrome[5]	62	13
Nonspecific Syndrome[6]	90	18.9
High Urinary Syndrome[7]	16	3.4
Lower Urinary Syndrome[8]	30	6.3
Total	477	100

[1] *Consumptive syndrome – clinical syndrome characterized by consuming the body's reserves, secondary to the evolution of serious chronic diseases.*

[2] *Dysmotility-like dyspepsia – bloating, abdominal distention, flatulence, and prominent nausea.*

[3] *Biliary Syndrome – abdominal pain, especially in the upper right side of the abdomen under the rib cage, nausea or vomiting*

[4] *Dyspeptic Ulcer-Like Syndrome – discomfort or pain that occurs in the upper abdomen, often after eating or drinking.*

[5] *Abdominal Pain Syndrome – continuous or almost continuous abdominal pain, slightly related to intestinal function, associated with decreased daily tone, and which has been present for at least the last six months.*

[6] *Nonspecific Syndrome – Indigestion, abdominal pain with bowel movements, feeling full after eating a small amount of food, nausea, vomiting.*

[7] *High Urinary Syndrome – Painful urination (dysuria), frequent urination, especially during the day, pain in upper abdomen and back*

[8] *Lower Urinary Syndrome – blood in your urine (hematuria), difficulty urinating (urinary retention), feeling an immediate urge to urinate, frequent urination, especially during the day, painful intercourse (dyspareunia), painful urination (dysuria), pain in your genitals, lower abdomen and lower back.*

Correlation between the parameters in pathology where the ultrasound examination has a major role in the diagnosis such as lithiasis and proliferative disease

Correlations between biliary syndrome and cholelithiasis

Out of 38 patients who complained of biliary syndrome, only 4 were found biliary lithiasis ultrasound aspects, while out of 439 without the biliary syndrome, 25 (5.7%) had cholelithiasis Table 2. The differences are statistically insignificant (p -0.27). The absence of a syndrome in the anamnesis does not exclude a certain type of pathology. The usefulness of the ultrasound examination is obvious in this case.

Table 2: The relationship between biliary syndrome and cholelithiasis

P -0.27			Cholelithiasis		Total

[1] Lower urinary syndrome: difficulty urinating (urinary retention), feeling an immediate urge to urinate, frequent urination, especially during the day, painful intercourse (dyspareunia), painful urination (dysuria), pain in your genitals, lower abdomen and lower back pain with or without hematuria, fever, chills

Tele-ultrasound examination skills

We analyzed the examiner's ability to highlight the abdominal organs that present difficulties of ultrasound examination at the classical, direct examination. One of the factors that makes ultrasound examination difficult is obesity. That's why we analyzed the number of unchecked organs and the body mass index (BMI).

Number of unvisualized organs and body mass index (BMI)

In 41 cases an organ was not revealed, in 5 situations two organs were not visualized, in 4 cases – 3 organs, in one case – 5, respectively 9 organs. In cases where an organ has not been visualized, 4 (13.3%) people with obesity grade II are noted, or 17 (10.4%) overweight people. Situations with two unvisualized organs were identified in normal or overweight people Table 5.

Table 5: Relationship between BMI and number of organs not viewed

[1] BMI = weight (kg)/height (cm^2)

Relationship between tele-ecographist and spleen visualization

The spleen has the same characteristics in ultrasound examinations as kidneys: intestinal gaseous overlaps and the chest cage make it difficult to examine these organs. Therefore, we evaluated the feasibility of the method by establishing the vision rate of the spleen at each of the examiners included in the study. The results, contained in the table below, demonstrate the uniformity of this parameter and support the promotion of the patient's examination method (Table 6).

Number of unidentified organs during an examination

The first condition for correct examination is the honesty of the examiner; declaring the parameters unidentified during the examination makes sure that they will be evaluated in other conditions (e.g. after the treatment of reducing bloating, examination of the bladder in the replete or gallbladder of fasting) or with other imaging means: retroperitoneum by CT or MRI, prostate by an endorectal probe, genital organs by an endovaginal probe (Table 7).

		%	89.1%	8.6%	1.0%	0.8%	0.2%	0.2%	100.0%

The two cases in which no organ could be visualized were correlated with very low acoustic impedance, increased BMI, and difficulties in maintaining clinostatism and apnea, due to the accusation of comorbidities, in conditions of postprandial examination and with the bladder in vacuity. In these cases, the limits of the method are declared and the patient was guided to imaging methods compatible with their particularities.

DISCUSSION

The terms used in this study are based on the recommendations of EFSUMB 2018 in which it is specified that the ultrasound examination suggests diagnostic hypotheses, but does not make a diagnosis [10]. To extend the accumulated experience to other specialties, we analyzed the studies published in the following areas: emergency medicine, obstetrics, gynecology, cardiology, pediatrics, musculo-skeletal, and pneumology.

Portable ultrasound units were used in the initial phase of trauma resuscitation for Focused Assessment with Sonography for Trauma, based on triage protocols for trauma patients by paramedics emergency physicians: infield FAST or e-FAST examinations. The study demonstrated similar quality with original movies; after 20 min lecture on FAST and US system presentation TeleUS (FAST) for US naive paramedics by emergency physicians was performed FAST on a patient with real-time EP connection. The result of the study was 100% complete views, with a mean time of 262 seconds (< 5 minutes) [11].

Obstetrics and gynecology: lack of fetal radiation exposure make teleUS the perfect tool for geographically isolated pregnant patients. Confirmation of intrauterine pregnancy, monitoring of fetal growth, and evaluation of pregnancy-related complications, with markedly reduced costs, were demonstrated in the studies [12,13,14].

Echocardiography is indispensable in clinical decision-making remote fetal echocardiography congenital prenatal heart disease left ventricular systolic function, LV ejection fraction [15].

Remote spatial applications International Space Station applications, 2h pre-flight training modules, 60 min in-flight session, e-learning system for US operators, no consistent significant effects of long-duration space flight on echocardiographic variables [16,17,18].

The use of ultrasound in the examination of musculoskeletal structures exceeded the limit of the penetrability of ultrasound through the bone and allowed the opening of new horizons both in direct examination and by tele-echography including self-examination [19].

In pediatrics, the use of point-of-care ultrasonography (POC US) is very useful [20].

During the COVID-19 pandemic, it was necessary to use all diagnostic means including ultrasound, which proved to be a low-cost tool very useful in remotely guided pulmonary resuscitation [21].

Tele-echography in addition to teleconsultations is a unanimously accepted aid.

The main problem is the number of specialists needed to solve the increasing demand for tele-echography services. The solution can be to accredit the overspecialization of the nurses in synchronous tele-echography, and the use of artificial intelligence in the field of tele-ultrasound.

On the existing structure, other types of ultrasound examinations are carried out: echo cardio, thyroid echo, and peripheral eco doppler, which is the subject of ongoing studies.

In the future, networks, such as those described, can be organized in human communities such as militia units, refugee camps, children's camps, and theaters of battle.

CONCLUSION

Portable hand-held ultrasound devices will move this valuable medical investigation near the patient and the medical society must prepare for this stage.

Future research directions may be a combination of tele-consultation with other investigations that can participate in the diagnosis of the remote patient: tele-EKG, tele EEG, tele-dermatoscopy, tele-otoscopy, telemedicine stethoscope.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Acknowledgments

This work was supported by a grant from the Ministry of Research and Innovation project number ID P_34_498, within MFE 2014-2020-POC.

Authors' contribution

Conceptualization, Nicolau Carmen Daniela and Luiza Enache methodology, Cormos Bogdan; software, Adrian Tarta validation, and formal analysis, Adrian Saftoiu, investigation, Remus Sipos resources, Nicolau Carmen Daniela; writing—Nicolau Carmen Daniela; writing—review and editing, Adrian Saftoiu.; project administration, Bogdan Cormos. Abstract: *Objective: The study subject approaches a topic of cerebral pathology, namely the development of a pathological diagnosis that is as accurate as possible for the cerebral tumors and the metastases, using a new method that complements the optical microscopic examination and immunohistochemistry to correctly diagnose cerebral malignancies. Methods: Two-photon excitation (TPE) microscopy techniques are non-linear optical imaging methods that are gaining momentum in the investigation of fixed tissue sections, fresh tissue, or even for in vivo experiments. This method can be used for offering complementary information on the tissue architecture. We argue that using non-linear optical microscopy (which includes TPE microscopy) images collected on this category of brain tissue samples, can facilitate the interpretation of brain tumors and metastases, thus it is a solution worthy to explore. Scanning large areas of the lesions is important to avoid false-negative diagnoses because lesions are often non-uniform. Finding potential invasion sites is also restricted when using a narrow field-of-view imaging method. Results: Our study demonstrated that TPE microscopy can detect specific cellular features of cerebral tumors and metastases in good correlation with histopathological results. This approach can improve the accuracy of the cerebral tumors diagnosis and possibly other neoplasms. Conclusion: TPE microscopy is very important for future research because it could prevent the false or inadequate diagnosis of specific lesions and differentiate a primary tumor from a metastasis. The significance of the findings is attributable to cross-disciplinary cooperation and the constant use of a working standard across all of the experiments in this study.*

Keywords: *Two-photon excitation (TPE) microscopy, cerebral tumors, metastases, non-linear optical microscopy*

INTRODUCTION

Cerebral tumors are common in the general population and can present with focal neurological symptoms, seizures, or headaches, while some are asymptomatic and found incidentally. Cerebral metastases, meningiomas, and gliomas, particularly glioblastoma, are the most frequent types of cerebral tumors. Complex coordination of treatment between medical oncologists, radiation oncologists, neurosurgeons, and primary care physicians is necessary for the management of brain tumors and their consequences.

The term "primary cerebral tumors" refers to primary intracranial tumors that originate from the meninges, neuroepithelial tissues, pituitary and associated structures, cranial nerves, germ cells, blood-forming organs, or a distant subclinical primary tumor. In the United States, with an estimated 23,380 new cases identified in 2014 and 14,320 fatalities, malignant tumors are uncommon in adults. They accounted for 1.4% of all new cases of cancer and 2.4% of all cancer deaths. New cerebral tumors occur at a rate of 6.4 per 100,000 people annually, and their overall five-year survival rate is 33.4%. The peak occurrence follows between the ages of 55 and 64, and men are slightly more likely than women to experience it [1].

Primary cerebral tumors have a complex etiology, and genetics undoubtedly play a part in how they arise. The only environmental risk factor for primary brain cancers that has been scientifically validated is high-dose ionizing radiation exposure. There is little evidence that additional toxins or exposures raise the risk [2,3].

The World Health Organization assigns malignancy-grade tumors based on a combination of morphological characteristics, growth patterns, and molecular profiles. Primary cerebral tumors are categorized based on histopathologic criteria and immunohistochemistry data [4].

Primary cerebral tumor clinical symptoms might be general or specific. The cause of general symptoms like headaches and seizures is elevated intracranial pressure [5]. The compression or tissue breakdown of specific regions causes focal symptoms, such as unilateral weakness or personality abnormalities [6]. Early signs of low-grade tumors or early stages of illness are frequently focal before becoming more generalized as the tumor grows and spreads [7].

The typical perception of a tumor headache is that it is intense, worse in the morning, and accompanied by nausea and vomiting. But bifrontal, tension-type headaches are more frequently reported in people with cerebral tumors [8].

There is no distinct pathognomonic marker on imaging that distinguishes between main cerebral tumors and metastatic or nonneoplastic disease, despite the fact that imaging considerably reduces the differential diagnosis of primary cerebral tumors. Chest and abdomen CT may be helpful in situations of suspected or pathologically confirmed metastatic cancer, but pinpointing the location of the source tumor is frequently challenging, particularly when there are no clinical cues from the history and physical examination [9].

A skilled interdisciplinary team made up of experts in neurosurgery, radiation oncology, and medical oncology makes customized treatment decisions for each patient. The nature and location of the tumor, its likelihood of being malignant, the patient's age, and general health all factor into treatment considerations. Although surgery, radiotherapy, chemotherapy, or a combination of these may be used as the sole form of treatment, registration in clinical trials should be made available as an option for some high-grade malignancies [10].

The most safe and effective surgical removal of the tumor, followed by radiotherapy and chemotherapy, is the preferred course of treatment for primary brain tumors. Although the size of the resection is a predictive factor, the size of a safe tumor resection depends on the location of the tumor, the patient's performance, and most crucially, the patient's age [11].

After surgical resection, radiotherapy may be administered as the main treatment or as an adjuvant. Although brachytherapy, fractional stereotactic radiation, and stereotactic radiosurgery are other alternatives, standard fractionated external beam radiotherapy is the most used method. In some circumstances, combining radiation and chemotherapy has been demonstrated to increase survival [12].

In addition, it was studied with two-photon excitation (TPE) microscopy on mouse brains, even in-vivo, which may have an important role in our study [19].

This microscopy technique can be applied in many fields including physiology, neurobiology, embryology, and tissue engineering. Thin, almost transparent tissues (such as tegument cells) can be visualized in sharp detail high-speed imaging capabilities can also be used in the non-invasive optical biopsy. In cell biology, TPE microscopy has been used to produce localized chemical reactions. To detect cells and collagen in the cornea using intrinsic fluorophores (autofluorescence and second harmonic generation) as well as using extrinsic fluorophores [18].

Fluorescence microscopy based on (TPE) is a fluorescence-based imaging technique that allows imaging of tissue up to about one millimeter in depth due to reduced absorption and much lower scattering of emitted light. It has recently been applied in pre-clinical studies [18].

Fluorescence microscopy based on TPE does not require a filter in the emission path because it minimizes the loss of emitted radiation. The attenuation of excitation radiation due to scattering is also reduced because the scattering cross-section decreases with increasing wavelength. Near-infrared radiation used in two-photon excitation has several orders of magnitude less absorption in biological tissue than UV or blue-green radiation. A clear separation is achieved between the excitation and emission spectrum, ensuring the removal of excitation radiation and Raman scattering [20].

The discovery of potential sites of invasion is restricted by a limited wide field of view. One option for increasing the field of view, to be used in future research, is the acquisition of adjacent images and stitching these by using mosaicking algorithms. High penetration depth is important for imaging abnormal cells in cerebral tissue samples [20].

Over the past two decades, significant efforts have been made to advance the state-of-the-art in the clinical diagnosis of malignant dermatological disorders (e.g., non-melanoma skin cancers) [18]. However, the gold standard for the identification of such disorders continues to be conventional histopathology assays that call for the removal of small tissue fragments, fixation, staining, and subsequent bright-field microscopy examination. However, it must be remembered that these methods have significant drawbacks, including sample error, sluggishness, high costs, and interpretation unpredictability [13]. Due to these restrictions, there is a significant demand for faster, less invasive alternative diagnosis approaches that maintain the benefits of traditional histopathology, particularly those that relate to simple picture interpretation. These would steadily enhance the diagnostic workflows, lower related expenses, and finally result in increased survival rates of the patients [14].

Magnetic resonance imaging, optical coherence tomography, and more recently non-linear optical microscopy are some of the most promising approaches that have been put out to date for brain diseases. TPE microscopy is a prominent non-linear optical technique that offers supplemental data that has been shown to date to be extremely beneficial for determining tissue conditions. TPE microscopy entails the simultaneous absorption of two photons whose combined energy is sufficient to cause a transition to an excited state and the ensuing emission of a single photon with an energy that is only marginally less than the combined energy of the two excitation photons as a result of non-radiative processes (e.g., vibrational relaxation) [15].

Optical microscopy is a technology that can collect size and shape details from human tissues, but when the cell structure becomes poorly differentiated, the features of this technique are limited. The main limitations of optical microscopy are related to resolution (implicit in light diffraction) and the wavelength of the radiation used. So, the modifications that can be made to improve the spatial resolution and image contrast are by using radiation with shorter wavelengths, increasing the numerical aperture, or using a medium with a high refractive index. Using even a microscope with very good quality lenses, a well-aligned system, and the largest aperture, the resolution remains limited to half the wavelength used. Confocal scanning microscopy and multi-photon microscopy bring an improvement in both spatial and axial resolution limits [20].

The TPE microscopy technique is a non-linear optical imaging method. It is based on the excitation of a fluorophore by the simultaneous absorption of two photons in a single event. This method can be used to provide complementary information on tissue architecture [16].

In the case of two photons excitation, it is necessary that the wavelength of the photons is twice the wavelength of the photons used in the case of excitation using a single photon to obtain the same excitation energy, which corresponds to the difference between the energy of the ground state of the molecule and the of the excited state. At the same time, the two photons must reach the sample in a very short time (less than 10-16 s).

Since the emission of fluorescence by two-photon excitation depends on the simultaneous absorption of two photons with infrared wavelengths, the probability of two-photon absorption by a fluorescent molecule is a quadratic function of the excitation radiance [17].

MATERIALS AND METHODS

The use of nonlinear optical microscopy images (which includes TPE microscopy) collected on this category of cerebral tissue samples can facilitate the interpretation of cerebral tumors and metastases and is thus a solution worth exploring. Scanning large areas of lesions is important to avoid false-negative diagnoses, as lesions are often non-uniform.

In order to achieve an excitation based on the coupling of two photons (which has a low probability), it is necessary to have a lot of photons (thus strong laser radiation) at the same time and in the same place. This thing is achieved using a Ti: Sapphire laser with femtosecond pulses, where basically the photons will be in these pulses, and placing them in the same place is done with high numerical aperture objective lenses that focus the radiation in very narrow areas. As an excitation source, we used a Ti: Sapphire laser (Chameleon Ultra II, Coherent) tuned at 870 nm, with ~140 fs pulses and a repetition rate of 80 MHz. A 10× magnification and 0.3 numerical aperture (NA) objective was used for focusing the laser beam on the sample and for collecting the two-photon excitation signals.

The material was collected from patients who had a histopathological diagnosis after surgery ("Dr. Carol Davila" Central Military Emergency Hospital Bucharest). Tissue fragments were fixed in 10% formalin, embedded in paraffin, with paraffin block sections – 4-5 microns thick. Images were acquired on labeled samples (Hematoxylin & Eosin stained) on the basis of which histopathological diagnoses were made under a conventional light microscope and fluorescence was from Eosin.

The macroscopy technique has been adapted to the particularities of each individual surgical specimen provided that the following requirements are:
- macroscopic description of the specimen and all macroscopic lesions;
- taking fragments of all macroscopically identified lesions, as far as possible including both macroscopically pathological and normal tissue in the same fragment;
- harvesting of fragments from the resection margin; if the macroscopically identified lesion was at a great distance from the resection margin (not being possible to include both lesion and resection margin in the same tissue fragment at the same time), the resection margin could be harvested parallel to the

plane of the incision; if the lesion was located close to the resection margin, harvesting perpendicular to the plane of the incision so that, after microscopic examination, the distance between the lesion and the resection margin could be measured. In the case of tumor pathology, this type of approach makes it possible to establish the completeness of the resection within oncological safety limits.

The final product is the permanent histopathological preparation which allows correct interpretation to establish the pathological diagnosis.

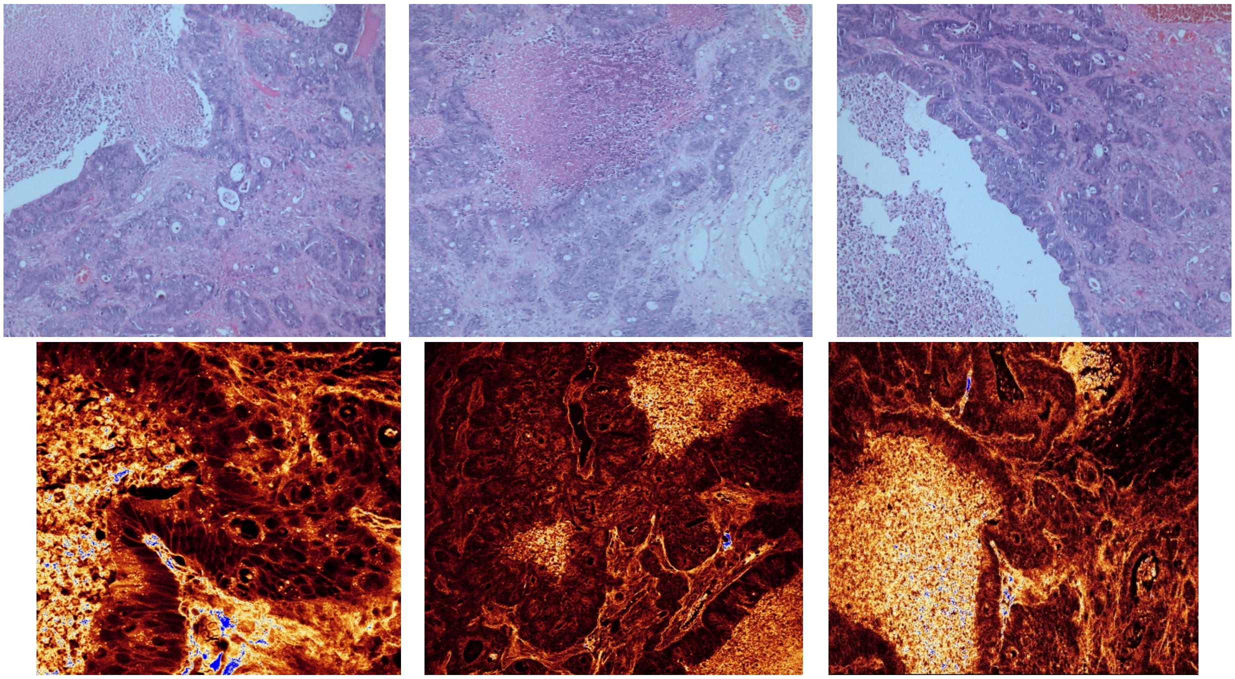
It worked according to the protocol of the Pathology Department of the Central University Emergency Military Hospital. For example, different reagents may be used, and the time of action and concentrations mentioned in the recipes are indicative and are adapted according to local conditions (ambient temperature, hardness, and pH of tap water). The technique used is considered correct if the results expected by the staining are obtained. Variations in the recommended staining recipes are allowed, depending on the structure to be revealed.

RESULTS

The standard of the histopathological technique requires the transformation of an organ or tissue specimen from an opaque tissue mass into a fine, translucent preparation that allows microscopic visualization of tissue structural details.

We made an analysis of the images acquired with fluorescence microscopy based on TPE and we'll try in future research to develop the earliest possible diagnosis of cerebral tumors based on distribution and tissue architecture. We acquired images for both a primary cerebral tumor and a secondary (metastatic) tumor.

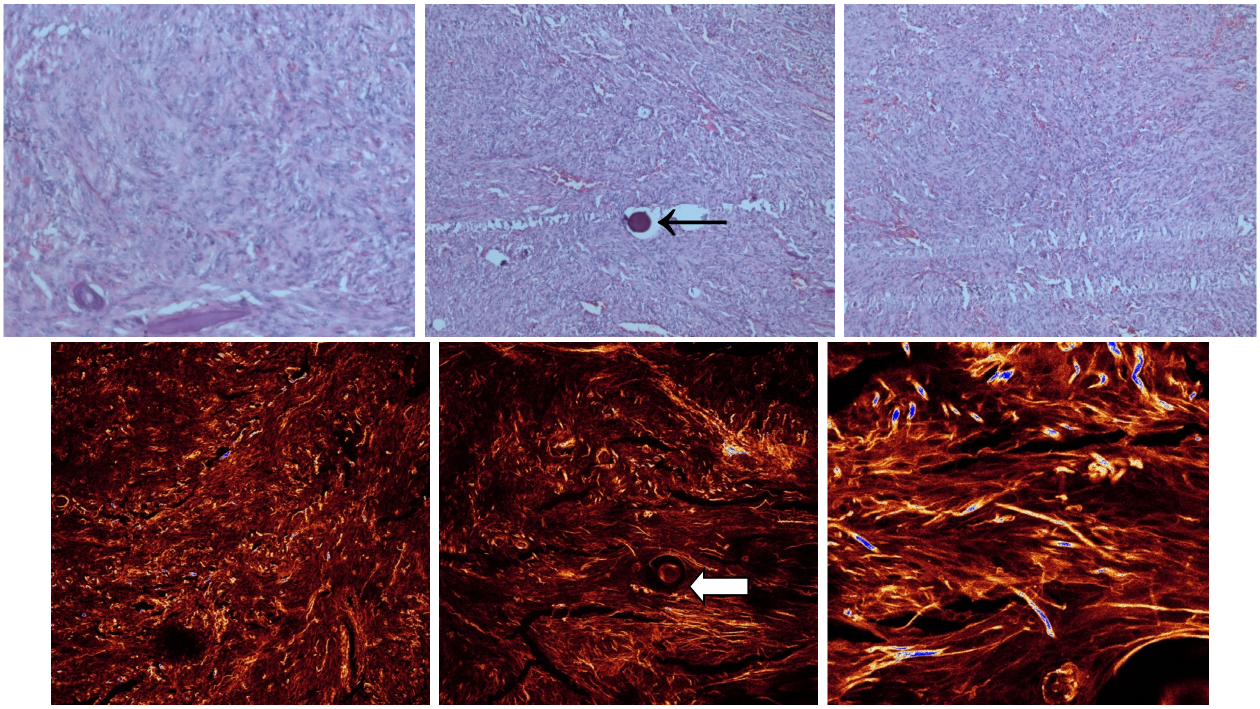
Figure 1: Cerebral adenocarcinoma metastasis - (a), (b), (c) - Bright-field microscopy image of Hematoxilin&Eosin-stained section - low magnification: (a) cerebral adenocarcinoma metastasis with necrotic debris inside the luminal of tumoral glands (top left corner) (b) cerebral adenocarcinoma metastasis with necrotic debris inside the luminal of tumoral glands (in the center of the image), (c) cerebral adenocarcinoma metastasis with necrotic debris inside the luminal of tumoral glands (bottom left corner); (d) TPE microscopy image for stained section (a), which clearly shows the desmoplastic stroma with collagen fibers by the bright orange-yellow; (e) TPE microscopy image for stained section (b); (f) TPE microscopy image for stained section (c).



In Figure 1 (a) – cerebral adenocarcinoma metastasis with necrotic debris inside the luminal of tumoral glands (top left corner), 1(b) – cerebral adenocarcinoma metastasis with necrotic debris inside the luminal of tumoral glands (in the center of the image) and 1 (c) – cerebral adenocarcinoma metastasis with necrotic debris inside the luminal of tumoral glands (bottom left corner) acquired images, we can visualize tumor proliferation composed of medium-sized cells grouped in glandular structures with a cribriform, tubular and solid pattern, associated with extensive areas of necrotic debris and desmoplastic stroma – like a colonic adenocarcinoma metastasis in the right occipital lobe, with a history of a colon neoplasm.

In Figure 1 (d) (e) (f) acquired TPE microscopy images we can observe the glandular tumor structures represented in dark red, and the lakes of necrotic debris and desmoplastic stroma with collagen fibers in bright orange-yellow, with the mention that the areas of necrotic debris are punctate and brighter, and the collagen fibers in the desmoplastic stroma are represented by linear-wavy curves.

Figure 2: Atypical meningioma - (a)(b)(c) - Bright-field microscopy image of Hematoxilin&Eosin - stained section - low magnification; (a) Atypical meningioma with spindle cells with increased cell density areas; (b) Atypical meningioma with true psammoma body (black arrow); (c) Atypical meningioma with early ages psammoma bodies according to their level of calcification) and vascular spaces; (d) TPE microscopy image for stained section (a); (e) TPE microscopy image for stained section (b) – psammoma body (white arrow); (f) TPE microscopy image for stained section (c), but with high magnification to highlight the vascular spaces detectable on the Hematoxilin&Eosin-stained section (light blue).



In Figure 2 (a), (b), (c) images, we detect a primary cerebral tumor in the left parietal lobe. We can observe on the Hematoxilin&Eosin-stained section, a tumor proliferation consisting of spindle cells with increased cell density, cellular atypia, and the presence of calcospherites well represented also in two-photon excitation microscopy from Figure 2 (d), (e), (f). Calcospherites or psamomma bodies are concentric calcifications of meningothelial cell nests (concentric laminated eosinophilic bodies) with different ages depending on their level of calcification. A true calcospheritis is well represented (black arrow) in a Bright-field microscopy image of Hematoxilin&Eosin – Figure 2(b). Histopathological features are consistent with atypical meningioma.

In Figure 2 (f) Corresponding two-photon microscopy image for stained section (c) – low magnification, we acquired two-photon excitation microscopy images at high magnification to highlight the vascular spaces (light blue) detectable in the standard Hematoxylin&Eosin-stained section.

DISCUSSION

Our study demonstrated that TPE microscopy can detect specific cellular features of atypical meningioma (primary cerebral tumor) and colonic adenocarcinoma (cerebral metastases) in good correlation with histopathological findings and even differentiate them.

Although such efforts are very valuable and play an important role in facilitating the interpretation of nonlinear optical data, it should be noted that a universal image processing or artificial intelligence method capable of generalizing and accurately addressing all tissue types is still lacking.

The use of this technique will also avoid the overuse of other relatively expensive complementary diagnostic techniques currently available (molecular biology techniques, genetic tests, IHC tests, electron microscopy, etc.).

The importance of the results obtained is due to interdisciplinary collaboration and the consistent application of a working standard throughout the experiments in this work. TPE microscopy has allowed us to obtain a global image of tissue because fluorescence has this advantage. Used as an additional technique with applicability in pathology could help to avoid underdiagnosis or overdiagnosis of some lesions, whose correct diagnosis is essential for proper and effective treatment.

CONCLUSION

Our research demonstrates that TPE microscopy can differentiate a cerebral metastasis from an atypical meningioma (primary cerebral tumor). Also with the help of two-photon excitation microscopy, it is possible to detect cellular, glandular, and vascular spaces, calcospherites in different stages, necrotic debris, and desmoplastic stroma structures. All of these are important tissue elements in diagnosing and differentiating certain tumor entities.

Abstract: *The term "panniculitis" refers to a heterogeneous group of conditions that involve inflammation of the subcutaneous cellular tissue. Although there is no universally accepted classification of panniculitis, to facilitate the diagnosis, they were divided into two large classes, based on the histopathological criteria: predominantly lobular and predominantly septal panniculitis. Depending on the presence or absence of vascular damage, each of the two classes mentioned above is divided in turn into panniculitis without vasculitis and panniculitis with vasculitis. The diagnosis of various types of panniculitis can sometimes be very difficult, due to the histopathological changes that occur in the various evolutionary stages of the lesions. Thus, the positive diagnosis relies on the corroboration of clinical data, histopathological examination, and ancillary laboratory tests. We provide an overview of the clinical and histopathological features of panniculitis, classified according to the histopathological criteria.*

Keywords: *panniculitis; inflammation; vasculitis; necrosis; subcutaneous tissue*

INTRODUCTION

The term "panniculitis" refers to a heterogeneous group of conditions that involve inflammation of the subcutaneous cellular tissue. The clinical and histopathological diagnosis of panniculitis is difficult to establish, this group of conditions being considered "the ugly duckling of dermatopathology", firstly because their deep localization does not allow the clinician to identify characteristic aspects for each type of panniculitis and secondly because of the inadequate sampling of the biopsy piece, which is often not deep enough.

Clinically, most panniculitis is characterized by the occurrence of erythematous nodules, that are not pathognomonic for a particular clinical subtype. A careful anamnesis, location, and evolution of the lesions, symmetry, age of onset, and association with systemic signs and symptoms must be taken into consideration for the clinical diagnosis.

Histopathological examination is a useful tool for a positive diagnosis. It is necessary to perform a deep incisional skin biopsy, which should also include subcutaneous cellular tissue, from an early-stage, evolving nodular lesion. Lesions in advanced stages usually show microscopic changes of lipoatrophy and sclerosis, leading to an inconclusive result of the histopathological examination [1,2].

Several histopathological features need to be considered in order to correctly classify panniculitis, mainly the location of the inflammatory infiltrate (septal, lobular) and the presence or absence of associated vasculitis. Based on these criteria, panniculitis is divided into septal and lobular panniculitis with or without vasculitis and if it exists, the size of the affected vessels can guide the diagnosis. Further details such as the type of adipocyte necrosis, the type of inflammatory cells, or the presence of granulomas may contribute to a more precise diagnosis. Although it is considered that all panniculitis is mixed panniculitis since the inflammatory infiltrate can be highlighted both in the lobules and the septa, based on where it predominates the condition may be classified into a predominantly lobular or a predominantly septal form [1,3].

Necrosis of adipocytes is another aspect that can be observed during the histopathological examination of panniculitis, these appearing either in the form of elements that have completely lost their cellular structure or in the form of anucleated cells, depending on the type of necrosis.

The most frequently encountered type of adipocyte necrosis is lipophagic necrosis, the so-called foamy macrophages, loaded with lipids, obtained by digesting dead adipocytes, being objectified during microscopic evaluation. Their cytoplasm can be granular or pale, with multiple microvacuoles. Lipodermatosclerosis and traumatic panniculitis are typical examples of this type of necrosis [1,3,4].

The hyalinizing necrosis of the adipose tissue consists of adipocytes with a homogeneous glassy protein material in the cytoplasm, altering the cellular structure. This type of necrosis is most often found in lupus panniculitis [1,3,4].

Another type of adipocyte necrosis is represented by liquefactive necrosis, which consists of granules formed by amphophilic detritus. This type of necrosis is frequently encountered in pancreatic panniculitis and in alpha-1-antitrypsin deficiency panniculitis. In pancreatic panniculitis, a subtype of liquefactive necrosis is objectified, the so-called enzymatic necrosis, which consists in the saponification of the cytoplasmic lipids in the adipocytes by the circulating pancreatic lipase [1,3,4].

Ischemic necrosis of the adipose tissue usually occurs in the center of the lobules, initially as anucleated adipocytes, but if the ischemia persists, lipophagic necrosis changes can also be observed, as seen in erythema induratum of Bazin [1,3,4].

Membranous necrosis of adipocytes represents an advanced stage of necrosis that consists of the appearance of an amphophilic or eosinophilic border of degraded cellular organelles. This type of necrosis is a histopathological change constantly encountered in sclerodermiform dermohypodermitis, but it is not specific to it, as it can be observed in almost all advanced stages of panniculitis [1,3,4].

The final aspect to take into account during the microscopic examination of the skin fragment is the type of cells in the inflammatory infiltrate [1,3,4].

In predominantly lobular panniculitis, in which the histiocytic inflammatory infiltrate predominates, septal sclerosis associated with a history of radiotherapy is suggestive of post-radiation panniculitis, while the microscopic objectification of crystals may be suggestive of panniculitis associated with gout, fat necrosis of the newborn, crystal storing panniculitis or panniculitis after administration of corticosteroids. Evidence of an inflammatory infiltrate rich in histiocytes, with no evidence of crystal, should direct the diagnosis towards posttraumatic panniculitis, lipoatrophy, or subcutaneous sarcoidosis, while cytophagocytosis suggests a possible cytophagic panniculitis [5].

In predominantly lobular panniculitis, in which an inflammatory infiltrate rich in neutrophils associated with foreign bodies is evident, we lean towards factitial panniculitis, while the presence of bacteria, fungi, or protozoa suggests infectious panniculitis. In the case of a predominantly lymphocytic infiltrate, the presence of lymphoid follicles and plasma cells is suggestive of the diagnosis of lupus panniculitis, while the location of infiltrate perivascularly in the deep dermis and subcutaneous adipose tissue tilts the scale towards the diagnosis of cold panniculitis. Last, but not least, the infiltrate without inflammatory cells leads to the diagnosis of sclerema neonatorum, if it is associated with needle-shaped crystals located in the center of fat cells, to calciphylaxis or oxalosis if calcifications are observed in the blood vessels or to sclerosing panniculitis if the microscopic examination shows necrosis in the center of the fat lobules [5].

In predominantly lobular panniculitis associated with vasculitis, the size of the affected blood vessels must be determined, venules damage suggesting either neutrophilic nodular panniculitis, Lucio phenomenon, or erythema nodosum leprosum, while damage of the arteries and veins is highly suggestive for erythema induratum, also known as nodular vasculitis [4,5].

In predominantly septal panniculitis that does not associate vascular damage, in which the histiocytic inflammatory infiltrate predominates, the radial granulomas in the septa are suggestive of erythema nodosum, while the microscopic objectification of cholesterol clefts may be suggestive of xanthogranulomatous necrobiosis. Evidence of an inflammatory infiltrate rich in histiocytes, associated with fibrin directs the diagnosis toward a rheumatoid nodule, while the association with mucin suggests a possible subcutaneous annular granuloma [5].

The histopathological examination of an inflammatory infiltrate made up of lymphocytes and plasma cells, associated or not with granulomatous infiltrate, in a patient with predominantly septal panniculitis tilts the scale towards the diagnosis of necrobiosis lipoidica, respectively deep morphea.

Predominantly lobular panniculitis is divided into forms with vasculitis of large vessels, such as nodular vasculitis, and forms without vasculitis, such as alpha-1-antitrypsin deficiency, cold panniculitis, sclerosing panniculitis, calciphylaxis, lupus panniculitis, pancreatic panniculitis, infectious panniculitis, traumatic panniculitis, polymeric microemboli from the coating of intravascular devices and histiocytic panniculitis with cytophagy and subcutaneous T-cell lymphoma.

Predominantly septal panniculitis without vasculitis may be found in erythema nodosum, rheumatoid nodule, lipoid necrobiosis, and eosinophilic fasciitis [6,7].

Predominantly septal panniculitis associated with vasculitis is divided according to the caliber of the affected vessels into panniculitis with vasculitis of large vessels and panniculitis with vasculitis of small vessels. If the affected vessels are represented by arteries, the suspected diagnosis is cutaneous polyarteritis nodosa, while the damage of veins suggests potential superficial thrombophlebitis. Venule involvement in a patient with panniculitis indicates leukocytoclastic vasculitis [8].

MOSTLY LOBULAR PANNICULITIS WITH VASCULITIS

Nodular vasculitis (Erythema induratum)

Nodular vasculitis is the most common form of predominantly lobular panniculitis with vasculitis, firstly described by Bazin in 1861, as firm, erythematous, indurated plaques and nodules, located predominantly on the dorsal side of the calves, more frequently in middle-aged obese women, with a history of thrombophlebitis, chronic venous stasis or cooling [9].

Although tuberculosis is the most frequent infectious triggering factor incriminated in the etiopathogenesis of nodular vasculitis, this being considered a "reactive disorder", there are also cases of the disease in which no trigger factor has been identified [10,11]. Many factors have been cited in the etiopathogenesis of erythema induratum, both non-infectious (hypothyroidism, chronic lymphocytic leukemia, superficial thrombophlebitis, rheumatoid arthritis, various drugs) and infectious (tuberculosis, group B and C hepatitis, Fusarium, Nocardia, Pseudomonas).

Clinically, erythema induratum appears as recurrent episodes of firm, indurated, erythematous nodules and plaques, located symmetrically on the dorsal side of the limbs, where the adipose tissue is well represented and the covering skin is cyanotic and cold. Nodules appear slowly, usually during winter and some of them ulcerate, discharge an oily material, then slowly heal, leaving atrophic scars.

Nodular vasculitis is characterized by a granulomatous type of inflammation that occurs as a specific response mediated by T lymphocytes to an antigen or as a type IV hypersensitivity reaction [12].

Acute cases of erythema induratum and infectious panniculitis present similar microscopic features, such as basophilic zonal necrosis and neutrophilic inflammatory infiltrate, which is why cultures and special stains for bacteria and other microorganisms are performed to exclude an infectious cause of panniculitis. In nodular vasculitis, microorganisms are never detected on special stains [13].

Histopathologically, nodular vasculitis is predominantly lobular panniculitis. In the early stages, a discrete inflammatory infiltrate with neutrophils can be detected in the lobules, but during the course of the disease, extensive areas of ischemic necrosis of the lobular adipocytes can be observed. The necrotic adipocytes are ingested by the histiocytes that later transform into foam cells. The histopathological examination of the nodular vasculitis lesions shows a characteristic aspect of granulomatous inflammation, the inflammatory infiltrate is composed of multinucleated giant cells, epithelioid histiocytes, and lymphocytes. In case of severe vascular damage, extensive areas of caseous necrosis can be noted, microscopically similar to tuberculosis lesions [14]. The type of inflammatory infiltrate also varies depending on the age of the lesions, so that in the early stages an inflammatory infiltrate predominantly composed of neutrophils is observed, while in the advanced stages of the disease, the inflammation is lymphocytic or granulomatous.

Once the histopathological diagnosis is established, it is necessary to evaluate a possible association with tuberculosis. In this sense, a chest x-ray, a Mantoux tuberculin test, and/or an interferon-gamma release assay test are performed. If one of the last two is positive, the patient will follow 9 months of triple tuberculosis therapy [15,16].

MOSTLY LOBULAR PANNICULITIS WITHOUT VASCULITIS

Panniculitis due to alpha-1-antitrypsin deficiency

Alpha-1-antitrypsin (AAT) is a circulating inhibitor of serine proteases. It inhibits the enzymes involved in the proteolytic degradation of tissues, has effects on the immune system, and inhibits complement activation. Severe deficiency can be associated with systemic diseases, such as pulmonary emphysema, pancreatitis, liver cirrhosis, glomerulonephritis, rheumatoid arthritis, vasculitis, and/or angioedema. Rarely, AAT deficiency is associated with recurrent lobular panniculitis and necrosis of the subcutaneous fat tissue. Patients with a partial deficiency may present panniculitis without systemic symptoms.

Clinically, panniculitis due to alpha-1-antitrypsin deficiency appears as recurrent, painful, erythematous plaques and nodules, with a proximal distribution on the hips, thighs, and buttocks, being most often induced by local trauma.

Characteristic of this type of panniculitis is the fact that the nodules ulcerate and suppurate, discharging an oily fluid, and heal with scarring.

The diagnosis is established on clinical, paraclinical, and histopathological criteria. The dosage of the serum AAT level and the evaluation of the AAT phenotype is indicated.

Histopathology shows in the early stages neutrophilic panniculitis in the reticular dermis and between the collagen bundles, followed by necrosis and destruction of adipocytes. Even though primary leukocytoclastic vasculitis is absent, secondary lymphocytic vasculitis may be found in areas with heavy neutrophilic infiltration and thrombosis [17].

Cold panniculitis

The cold panniculitis is a form of panniculitis that occurs most frequently in children exposed to extremely low temperatures or during winter, in people wearing tight pants that do not provide adequate thermal insulation and restrict blood supply to the subcutaneous fatty tissue [18,19].

Clinically, one can notice marbled, reddish-blue plaques similar to frostbite, located on the thighs and buttocks. If the affected skin areas are kept warm, the skin lesions disappear after a few days, without scars.

During the histopathological examination, an inflammatory infiltrate consisting of histiocytes and lymphocytes located in the adipose lobules can be noted, sometimes associated with edema in the papillary dermis and an extension of the inflammatory infiltrate in the dermis, the microscopic appearance being similar to that of perniosis [20].

Sclerosing panniculitis

Sclerosing panniculitis, also known as sclerodermiform dermohypodermitis or lipodermatosclerosis, is a complication of venous stasis, more common in women characterized by chronic inflammation, fibrosis, and progressive induration [21, 22].

Clinically, in the early stages, lipodermatosclerosis appears as erythematous-purple, indurated, imprecisely demarcated, painful plaques, similar to cellulitis, while in late stages, it appears as a woody plaque, with well-defined edges, hard on palpation. Fibrosis is accentuated in the subcutaneous tissue, and eventually, the leg takes on the appearance of an inverted champagne bottle.

The main etiological factor of lipodermatosclerosis is chronic venous insufficiency of the lower limbs, causing sludging in the lobular capillaries, with ischemia and necrosis of the central portion of the adipose lobules. [23]

Other factors involved in the etiopathogenesis of lipodermatosclerosis are represented by reduced plasma fibrinolytic activity, protein S and C deficiency, and excessive collagen production [24,25].

Histopathologically, the characteristic changes of stasis dermatitis are noticeable in the superficial dermis, while in the papillary dermis, there is a proliferation of capillaries and venules, fibrosis, and abundant deposition of hemosiderin. In the early stages, small amounts of inflammatory infiltrate, predominantly composed of lymphocytes, distributed among the collagen bundles of the septa are found, while in the center of the lobules, "ghost" outlines of the anucleated necrotic adipocytes can be observed. In the advanced stages of the disease, septal sclerosis is the main histopathological change. Other histopathological changes that can be objectified are represented by foci of necrotic keratinocytes, simultaneously with areas of extravasated erythrocytes and vascular congestion [24,25].

The diagnosis of lipodermatosclerosis is based on clinical criteria, the biopsy not be indicated due to the difficult healing given by the vascular damage and the risk of developing ulcers at this level. In the advanced stages of the disease, sclerosing panniculitis requires a differential diagnosis with conditions associated with diffuse induration in the lower limbs, such as scleromyxedema, morphea, erythema nodosum, myxedema, necrobiosis lipoidica, eosinophilic fasciitis, as well as another panniculitis.

Calciphylaxis

Calciphylaxis is a condition with a high mortality rate that occurs frequently in patients with chronic kidney disease undergoing dialysis. Calcium deposits in the middle tunic of the small arteries from the skin lead to thrombosis and ischemic necrosis with the appearance of refractory ulcers involving the lower extremities, the abdomen, and the gluteal region [26]. Major risk factors for calciphylaxis are end-stage renal disease, phospho-calcium metabolism imbalance, and primary and secondary hyperparathyroidism, while non-uraemic risk factors include female sex, obesity, diabetes, hypo-albuminemia, autoimmune diseases, warfarin use, protein C and S deficiency, active neoplasia or liver damage in a toxic-metabolic context [27].

Clinically, the lesions are similar to those in livedo reticularis, appearing as marbled, red-violet teguments, with reticular discoloration, reflecting the impaired vascular flow from the superficial dermis. Another variant of the appearance of calciphylaxis lesions can be painful erythema, with a marbled appearance and a sudden onset on the calves or on the feet, evolving into hardened plaques that later become necrotic and ulcerated. Other skin signs may include pathergia (ulceration triggered by minor trauma), recurrent digital ischemia, penile necrosis, and subcutaneous nodules on the breasts and abdomen. Extremely rare, patients can associate concomitant systemic damage such as proximal myopathy, aortic valve damage, or pulmonary calciphylaxis [26,27].

The main histopathological aspects objectified in patients with calciphylaxis are calcifications in small arteries, vascular thrombosis, and intimal hyperplasia (endarteritis obliterans) [28].

Lupus panniculitis

Lupus panniculitis is a chronic form of recurrent panniculitis, which affects women more frequently, the skin lesions being predominantly located on the buttocks, arms, shoulders and face [29].

Clinically, it presents itself as deeply located subcutaneous plaques or nodules, while the adjacent skin may present lesions of discoid lupus erythematosus. The regression of lupus panniculitis lesions can result in the loss of subcutaneous cellular tissue, with atrophy, this being a deforming complication. Subcutaneous nodules can calcify or ulcerate [30].

During the histopathological examination, approximately half of the cases of lupus panniculitis show changes in the epidermis and dermis similar to those in discoid lupus erythematosus, such as vacuolization at the dermo-epidermal junction, epidermal atrophy, mucin interposition between the collagen fibers in the dermis, thickening of the basement membrane or the presence of a lymphocytic inflammatory infiltrate in the dermis, while in the other half of the cases, the pathological changes of lobular panniculitis are located strictly in the subcutaneous adipose tissue [31,32]. A quite characteristic aspect of this type of panniculitis is represented by the presence of lymphoid follicles, with a germinal center and numerous plasma cells on the periphery and between the collagen fibers of the septa of the subcutaneous adipose tissue [33]. Although they are quite specific for lupus panniculitis, they can be objectified on microscopic examination in other conditions as well, such as erythema nodosum, erythema induratum of Bazin, morphea, subcutaneous panniculitis-like T-cell lymphoma or in panniculitis associated with dermatomyositis. In the late stages of this disease, hyaline fibrosis and calcification can be noticed. Membranous necrosis is also common in this stage of the disease. In the microscopic examination of the lesions collected from these patients, an inflammatory infiltrate rich in eosinophils can be objectified. The low titer of antinuclear antibodies does not exclude the diagnosis of lupus panniculitis [34,35].

Dermatomyositis is another systemic collagenosis that can be associated with panniculitis and requires a differential diagnosis with lupus panniculitis. Vasculitis with lymphocytic or neutrophilic infiltrate, the thickening of the walls of the subcutaneous vessels, and the presence of calcifications tip the scaling towards the diagnosis of panniculitis associated with dermatomyositis [36].

Eosinophilic fasciitis and deep morphea present histopathological diagnostic criteria (plasma cell-rich lymphoid infiltrates, fibrous thickening of the interlobular septa, eosinophils occasionally) and clinical (nodules and indurated plaques) are similar to lupus panniculitis. However, the absence of hyaline necrosis and the absence of dermo-epidermal changes (epidermal atrophy, thickening of the basal membrane, orthokeratosis, vacuolar degeneration of the basal layer, prominent dermal mucin) exclude the diagnosis of lupus panniculitis.

Subcutaneous panniculitis-like T-cell lymphoma is characterized by the "rimming" of adipocytes by atypical cytotoxic T cells, which get intensely colored when in contact with proliferation markers. The absence of lupus skin signs and nodular aggregates of lymphoid B cells excludes the diagnosis of lupus panniculitis. From a clinical point of view, there are no differences between lupus panniculitis and subcutaneous panniculitis-like T-cell lymphoma, but the persistence of the lesions, their rapid evolution, and absence of regression point the diagnosis towards lymphoma.

Immunofluorescence studies can be performed, objectifying the presence of linear deposits of C3 and IgM along the dermo-epidermal junction [31].

Pancreatic panniculitis

The pancreatic panniculitis is a form of panniculitis rarely associated with certain pancreatic diseases, such as pancreatic islet cell tumors, acinar cell carcinoma, pancreatic pseudocysts, acute or chronic pancreatitis, ductal adenocarcinoma or post-traumatic pancreatitis [38].

Clinically, pancreatic panniculitis appears as erythematous or red-brown subcutaneous nodules, painful or not, sometimes with a soft center, usually located on the lower limbs, but they can also appear on the arms, buttocks, or trunk. In mild cases of the disease, they heal with atrophic scars, while in severe cases, they can ulcerate and discharge a sterile, brownish, oily material, representing necrotic fat [39]. It can be associated with pleurisy or necrosis of the periarticular tissue [40]. Skin signs can appear a few months before the manifestation of the pancreatic disease. Circulating lipase and amylase are responsible for adipose tissue necrosis in pancreatic panniculitis. Disseminated necrosis of fatty tissue is associated with a high rate of mortality [41].

In pancreatic panniculitis, unlike other predominantly lobular panniculitis, it is preferable to take a skin biopsy from an established lesion. The histology of pancreatic panniculitis is characteristic, an important necrosis of adipose tissue being observed, as well as the appearance of the so-called "ghost cells", which are the former adipocytes that now present a thick, ghostly wall, the cell membrane not being destroyed by lipase. The latter present in the cytoplasm a granular, basophilic material, called calcium soap, which resulted from the combination of fatty acids with calcium ions [42,43].

In the early stages of pancreatic panniculitis, the characteristics of predominantly septal panniculitis determined by the pancreatic enzymes that reach this level through the permeable vascular walls are noted. Identifying the specific microscopic aspects of pancreatic panniculitis can be difficult also in the advanced stages of the disease, in which the structure of the fat lobule is completely replaced by a granulomatous inflammatory infiltrate, made up of multinucleated giant cells and foamy macrophages.

Severe cases of pancreatic panniculitis, associated with a history of pancreatic damage, are relatively easy to diagnose, but the same does not happen in mild cases. These lend themselves to differential diagnosis with erythema induratum of Bazin, infectious panniculitis, erythema nodosum, panniculitis associated with alpha-1 antitrypsin deficiency, aspergillosis, subcutaneous mucormycosis, and subcutaneous metastatic deposits [44,45].

MOSTLY SEPTAL PANNICULITIS WITH VASCULITIS OF THE LARGE VESSELS

Cutaneous polyarteritis nodosa

Cutaneous polyarteritis nodosa is a necrotizing vasculitis that affects the muscular layer of the small and medium arteries in the deep dermis and subcutaneous tissue. The vital organs are not involved, but the disease is recurrent and chronic [46].

Clinically, subcutaneous polyarteritis nodosa lesions manifest as painful skin nodules, associated with palpable purpura, ulcers, and livedo reticularis in the lower limbs. Usually, the presence of a pseudo-influenza syndrome characterized by low fever, unwell general condition, myalgia, and arthralgia is also observed [47].

During the histopathological examination, vasculitis lesions are observed in the small and medium-sized arteries and arterioles from the septa of the upper half of the subcutaneous adipose tissue. The affected vessels have thickened walls, presenting an inflammatory infiltrate composed predominantly of neutrophils. The intima of the affected vessels has a target appearance on the cross-section, presenting an eosinophilic ring of fibrinoid necrosis. Cutaneous polyarteritis nodosa is characterized by the segmental damage of the arterial vessels and by the simultaneous existence of lesions in different stages of evolution [46].

Direct immunofluorescence studies objectify the presence of complement and IgM deposits in the walls of the affected blood vessels [48].

MOSTLY SEPTAL PANNICULITIS WITHOUT VASCULITIS

Erythema nodosum

Erythema nodosum is the most common type of panniculitis in general and the main type of predominantly septal panniculitis without vasculitis. Most cases appear between the second and fourth decade of life, more frequently in women [49]. Erythema nodosum may be a delayed hypersensitivity response to infection or another inflammatory disease. In approximately one-third of the cases of erythema nodosum, a cause could not be identified, but in the rest of the cases, bacterial, viral, fungal, and protozoal infections, drugs, inflammatory bowel diseases, Behcet's disease, sarcoidosis, pregnancy, various neoplasms were blamed as triggering factors [50-52]. Streptococcal infection is the most common cause in children, while in adults different drugs, pregnancy, and sarcoidosis have been reported as the main triggering factors [53].

From a clinical point of view, erythema nodosum lesions appear abruptly as firm, tender, erythematous, non-purpuric, warm nodules, approximately 1-5 cm in diameter, symmetrically distributed on the calves, pretibial, ankles, and knees, after a prodromal period characterized by altered general condition, fever, headache, arthralgia, and myalgia. Rarely, nodules can also appear on the arms or trunk. The nodules from this pathology never ulcerate and they heal without scars. Sometimes, gastrointestinal symptoms can be associated, such as nausea, vomiting, abdominal pain, or diarrhea. In evolution, the nodular lesions in erythema nodosum flatten, leading to the appearance of hematoma-like lesions with a blue-green hue. The lesions fade within 2-6 weeks, even faster in children, leaving behind lesions with a purple appearance, similar to bruises, which disappear slowly [54].

A particular chronic form of erythema nodosum is represented by subacute migratory nodular panniculitis or erythema nodosum migrans, much less frequent, characterized by the appearance of a single firm, indurated, erythematous plaque, which slowly expands to the periphery while it heals centrally [55].

Histopathologically, in the early stages, the microscopic evaluation can objectify an abundant inflammatory infiltrate, rich in neutrophils, which could create diagnostic difficulties. The thickening of the septa is not very important, being caused by the accumulation of inflammatory infiltrate, edema and hemorrhage at this level, and cells around the cleft-like spaces in Miescher's radial granulomas are predominantly neutrophils. In the advanced stages, the inflammation is much reduced, being replaced by lipoatrophy and fibrosis [56].

Chronic erythema nodosum lesions are characterized by thickening of the septa and a slightly abundant inflammatory infiltrate, associating phlebitis and extravasation of erythrocytes, while in erythema nodosum migrans there is marked thickening of the septa from adipose tissue, the presence of multiple granulomas made up of granulation tissue, multinucleated giant cells, and an important capillary proliferation, but without signs of phlebitis [57]. Currently, most authors consider that chronic erythema nodosum and erythema nodosum migrans represent different stages of evolution of the same condition [3]. A quite specific histopathological aspect for chronic erythema nodosum is represented by Miescher's radial granulomas, which consist of small nodular aggregates, well delimited, of histiocytes, agglutinated around a banana- or stellate-shaped fissure, but it can also be identified in other conditions such as Behcet's disease, erythema induratum, Sweet syndrome, necrobiosis lipoidica or nephrogenic fibrosing dermopathy [58].

Necrobiosis lipoidica

Lipoid necrobiosis is a condition characterized by a granulomatous inflammatory process that extends from the deep dermis to the subcutaneous cellular tissue, leading to the appearance of predominantly septal panniculitis. There were no cases of lipoid necrobiosis affecting only the subcutaneous adipose tissue cited in the literature, its inflammation being always secondary to the inflammation of the deep dermis. The pathogenesis of granulomatous inflammation is not fully understood, but many cases of necrobiosis lipoidica have been associated with diabetes mellitus, although it does not occur exclusively in diabetic people [59].

The clinical picture consists in the appearance of oval, reddish-brown, well-demarcated papules and plaques, that may present telangiectasias on the surface, with clearly defined, erythematous, raised, shiny edges, usually located pretibial. The lesions progressively expand and they have a tendency to merge. In older plaques, the center is more yellow and can be atrophic, the subcutaneous vessels being visible through its transparency. The plaques can ulcerate, but the surrounding skin remains intact, showing, in general, some characteristics of necrobiosis lipoidica [59].

The histopathological features of necrobiosis lipoidica, which overlap with those of granuloma annulare, include palisading granulomas composed mainly of histiocytes, which surround the modified collagen fibers from the dermis, the inflammation being able to extend to the subcutaneous cellular tissue, affecting mainly the septa [59].

The immunofluorescence studies performed on lesions in the early stages of necrobiosis lipoidica objectify the presence of complement and IgM deposits in the walls of the vessels from the affected territories and sometimes even along the dermo-epidermal junction [60].

Eosinophilic fasciitis (Shulman’s syndrome)

Eosinophilic fasciitis is a form of localized scleroderma, which affects the deep fascia and sets in suddenly, most of the time being triggered by intense physical exercises. In the initial phase, it can mimic cellulite [61].

From a clinical point of view, eosinophilic fasciitis appears as symmetrical, edematous, reddish-brown plaques, which do not show sensitivity to palpation, usually located on the limbs, which evolve into brown, indurated plaques with a pale center. The extension of sclerosis in the subcutaneous adipose tissue restricts the movements of the tendons of the affected limb [62].

From a histopathological point of view, the lesions in eosinophilic fasciitis are similar to those in subcutaneous scleroderma. The microscopic examination shows thickening and edema of the interlobular fibrous septa and the deep fascia. Both in the septa and the fascia, an abundant inflammatory infiltrate is observed, consisting of eosinophils, lymphocytes, plasma cells, and histiocytes. Occasionally, lymphoid follicles are also present in the septa. The lesions extend deeply, to the underlying fascia, but unlike scleroderma, which usually does not present an inflammatory infiltrate, Shulman's syndrome is characterized by an abundant eosinophil infiltrate in the fascia [63,64].

CONCLUSION

One of the first steps that should be performed in the histopathological examination of lesions suspected of being panniculitis, is to establish whether it is primarily a panniculitis or if it is a dermatitis with extension to the subcutaneous fatty tissue, especially in the septa, as it happens in conditions such as sarcoidosis, lipoid necrobiosis or scleroderma.

Although there is no universally accepted classification of panniculitis, to facilitate the diagnosis, they were divided into two large classes, based on the histopathological criteria: predominantly lobular and predominantly septal panniculitis. Depending on the presence or absence of vascular damage, each of the two classes mentioned above is divided in turn into panniculitis without vasculitis and panniculitis with vasculitis.

Once these two criteria have been established, the type of inflammatory infiltrate in which histiocytes, neutrophils, lymphocytes, or no inflammatory cells may predominate, is also an important element in the diagnosis of panniculitis that does not associate vascular damage, but this may not bring additional information, or it can even delay the diagnosis, since, in this group of conditions, the histopathological picture varies according to the clinical age of the lesions. Most panniculitis lesions begin with an inflammatory infiltrate predominantly composed of neutrophils, after which they pass either through a granulomatous phase or through a phase in which the histiocytic inflammatory infiltrate predominates, while finally, in the late stages, the inflammation is reduced or even absent. Since it is a difficult mission for the clinician to identify with the naked eye the lesions of panniculitis in early stages, those that end up being biopsied are, most of the time, in advanced stages, which is why they do not provide specific information regarding the type of panniculitis.

The diagnosis of panniculitis is difficult, but there are clinical diagnostic keys (location of lesions, symmetry, age of onset) and histopathological ones (type and location of inflammatory infiltrate, presence or not of vasculitis, presence or not of liponecrosis, membranocystic changes, atypia or cellular necrosis). The corroboration of clinical data with histopathological ones and with the results of additional paraclinical explorations depending on the histological classification leads to a positive diagnosis.

The nosological classification of panniculitis is essential for the optimal therapeutic approach, with some cases only needing follow-up, and others having a severe, potentially fatal course in the context of systemic diseases, serious infectious diseases, or neoplasias.

Abstract: *Pulmonary hypertension (PH) has gained more and more attention in the last years given the increased mortality and morbidity rate and in particular pulmonary arterial hypertension associated with autoimmune diseases (a specific subgroup of PH), entities with an increasing incidence and prevalence globally. Among these, systemic sclerosis is of particular interest, being the most common among connective tissue diseases (CTDs) with PH as a major complication. Other CTDs such as mixed connective tissue disease (MCTD), systemic lupus erythematosus (SLE), primary Sjogren's syndrome, and dermatomyositis may also develop PH as a complication of these severe and complex conditions, which can have a major impact on prognosis and quality of life. PH has also been reported in rheumatoid arthritis and ankylosing spondylitis but further studies are necessary. Several studies have shown that the 3-year survival rate for patients with systemic sclerosis-associated with pulmonary hypertension (SSc-PH) is between 31% and 52%, while the 5-year survival rate is below <50%. Therefore, an early and accurate diagnosis as well as subsequent management of PH in these conditions is mandatory, since survival remains suboptimal despite treatment advances. The aim of this article is to provide an overview of different autoimmune diseases associated with PH and to provide an easy reference source on current best practices.*

Keywords: *pulmonary hypertension; autoimmune diseases; connective tissue diseases; vasodilators; Raynaud phenomenon'*

INTRODUCTION

Pulmonary hypertension (PH) is a severe, progressive, and life-threatening disease that can often lead to premature death. Pulmonary hypertension (PH) describes a heterogeneous group of conditions that are defined by an increase in the mean pulmonary arterial pressure (mPAP) and pulmonary vascular resistance leading to an increase in the right ventricular (RV) afterload which results in RV overload and finally to right heart failure and even death. The most common causes of PH are left heart diseases and chronic lung diseases [1,2].

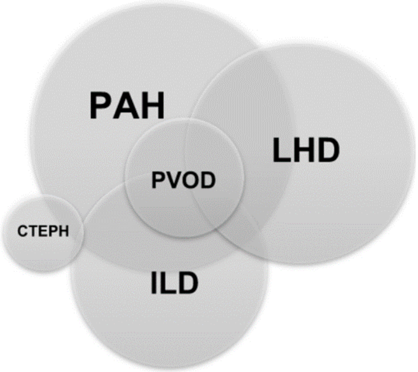
Patients with connective tissue diseases (CTDs) such as systemic sclerosis (SSc), mixed connective tissue disease (MCTD), systemic lupus erythematosus (SLE), primary Sjogren's syndrome, and dermatomyositis may develop PH as a complication of these complex conditions, which can have a major impact on prognosis and quality of life. In this review, PH is discussed among connective tissue diseases, with an emphasis on systemic sclerosis, which is the most common of all collagenoses that have PH as a complication. Therefore, new findings regarding epidemiology, early screening/ diagnosis, new therapeutic perspectives, and prognosis are brought to attention [3].

CLASSIFICATION

The current classifications of PH are based on clinical, physiopathological, and etiological similarities along with hemodynamic and treatment characteristics. PH is classified into five groups based on etiology: 1 – pulmonary arterial hypertension (PAH); 2 – pulmonary hypertension associated with left heart diseases; 3 – pulmonary hypertension associated with lung diseases; 4 – chronic thromboembolic pulmonary hypertension; 5 – pulmonary hypertension due to systemic or multifactorial conditions. The first group is also known as primary PH and the other four are under the common name of secondary PH [4].

Patients with CTDs such as SSc, MCTD, and SLE are at high risk of developing PH, especially with type 1-PAH (pulmonary arterial hypertension) as it is the most common and important due to its aggressiveness, short survival, and limited treatment options. In the last decades, the survival rate in this type of PH has improved, reaching 57% from the moment of diagnosis based on cardiac catheterization, but it is still suboptimal and continues to be a huge challenge [5]. At the same time, other forms of PH may appear in these patients, possibly an overlap of different forms of PH probably due to the autoimmune status of these conditions (Figure 1).

Figure 1: Different phenotypes of pulmonary hypertension in SSc-overlap. Abbreviations: CTEPH, chronic thromboembolic pulmonary hypertension; ILD, interstitial lung disease; LHD, left heart disease; PAH, pulmonary arterial hypertension, PVOD, pulmonary veno-occlusive disease; SSc, systemic sclerosis [Almaaitah, 2020].



Connective tissue diseases represent the second major cause of PAH, after idiopathic ones, occupying about a quarter of the total population with PAH. Group 2 of PH, which is associated with left heart diseases can also occur in these collagenoses. Interstitial lung disease (pulmonary fibrosis) is another common complication of these autoimmune diseases, especially SSc and MCTD, so type 3 PH may be present to the same extent in these patients. Of note is pulmonary veno-occlusive disease which is associated with a worse prognosis due to the lack of response to PAH therapy and the risk of pulmonary edema due to these treatments. This form of PAH occurs especially in patients with SSc [3].

Another definition refers to the hemodynamic component, thus PH was defined in the past as mean pulmonary artery pressure (mPAP) of ≥25 mmHg, but recently it has been updated according to the 6th World Symposium on Pulmonary Hypertension (WSPH) to an mPAP value >20 mmHg. Studies have shown that normal mPAP in healthy individuals is approximately 14±3.3 mmHg and the upper limit of normal is 20 mmHg. This new definition appears to be less practical but may be useful in diagnosing more individuals with PH, as symptoms usually begin at a much higher value above the normal upper limit (i.e. >50mmHg). Nonetheless, there is a major concern regarding inclusion in this group of healthy individuals.

Another major hemodynamic change recommended by the 6th WSPH is the inclusion of pulmonary vascular resistance (PVR) in the classification and definition of PH. Thus, PH is further subclassified as pre-capillary PH (pre-PH), isolated post-capillary PH (IpcPH), or combined pre- and post-capillary PH (CpcPH) based on pulmonary arterial pressure and PVR [5].

EPIDEMIOLOGY

The lungs are often affected in connective tissue diseases (CTDs), because of the systemic nature of these autoimmune pathologies and due to the complex anatomic-functional patterns of the respiratory apparatus. Among the CTDs, systemic sclerosis (SSc) has the highest prevalence of pulmonary involvement (between 70% and 90% of patients with CTDs) and PAH is developed in 8-12% of patients with SSc. The incidence of PAH in SSc is about 0,61 cases per 100 patients per year. The prevalence of PAH among other CTDs remains to be determined due to the lack of large studies, but it is estimated to be lower than in patients with SSc. The prevalence of PAH in SLE is <4% and for the other diseases in this group is <1% [3,7].

PATHOGENESIS AND DIFFERENT FEATURES OF PULMONARY HYPERTENSION IN DIFFERENT AUTOIMMUNE DISEASES

Systemic sclerosis (SSc) or scleroderma is a rare and complex systemic autoimmune disease that affects the skin and the internal organs through multiple processes including fibrosis and thickening of these structures and vascular abnormalities [8]. The two major complications that might occur are pulmonary fibrosis and pulmonary arterial hypertension (PAH). The presence of both complications is not random since they have overlapping mechanisms. It seems to appear an abnormal fibroproliferation that results from a vascular injury such as endothelial cell injury and consecutive dysfunction [8]. Pulmonary fibrosis and PAH might appear as a consequence of an increased number of vasoconstrictors and proliferative mediators (endothelin-1) and a decrease in vasodilators (nitric oxide and prostacyclin), therefore leading to progressive pulmonary arterial remodeling and increase in pulmonary vascular resistance [6].

Systemic lupus erythematosus (SLE) is a chronic, autoimmune disorder that presents with a multitude of signs and symptoms and it affects multiple internal organs including the lungs. The most common lung manifestation is pleuritis but the parenchyma and the vasculature may also be involved causing thickening of the arterial media and subintima and immune complexes deposition in the arterial wall. PAH can rarely be present in SLE but it is a life-threatening pulmonary manifestation caused by left ventricular dysfunction or congestive cardiac failure and also by interstitial lung disease and chronic thromboembolic disease. Nevertheless, there is an increased risk of PAH and pulmonary venous thromboembolism (VTE) in SLE patients especially when it is associated with antiphospholipid antibody syndrome. Among SLE patients, most cases with PAH developed in the presence of Raynaud's phenomenon (60% of cases) and positive rheumatoid factor [9]. Another association was found between PAH and anti-RNP antibodies [7,9].

Primary Sjogren syndrome (pSS) is an autoimmune disease characterized by impairment of exocrine glands (lacrimal and salivary) due to inflammatory infiltrate but it can also affect extra glandular organs, including the respiratory tract and lung involvement which are one of the most common complications leading to increased mortality. PAH can rarely appear in pSS but can lead to right heart failure and death. The exact prevalence of PAH in pSS is difficult to estimate but one study has shown a value of 22% of patients based on echocardiographic evidence, although right heart catheterization is the gold standard for the diagnosis; There is an association between pSS-PAH and hypergamma-globulinemia, positive ANA and anti-RNP antibodies [7].

Rheumatoid arthritis (RA) associated pulmonary hypertension is very rare and can be attributed to parenchymal lesions, vascular disease such as rheumatoid vasculitis or it can develop due to chronic thromboembolic disease. But rheumatoid arthritis can also be associated with other autoimmune diseases such as scleroderma, SLE, and other CTDs in overlap syndromes, therefore the diagnosis of PH can be more relatable to these conditions.

Moreover, even though there is no disease-modifying treatment of RA (DMARDs or bDMARDs) suspected of causing PH, it is common knowledge that Methotrexate can cause pulmonary fibrosis that can lead to PH. The role of these drugs on PH can not be evaluated due to a lack of data. PH seems to be more common in patients with seropositive forms and advanced radiological signs. Systematic screening of PH is not necessary for RA patients but if is suspected further diagnostic testing should be pursued. In the case of RA, the prevalence of PH is identical to that seen in the general population [11,12].

Ankylosing spondylitis (AS) is a systemic inflammatory disease affecting the axial skeleton and/or peripheral joints and can be associated with extra-articular manifestations including uveitis, aortitis, and valvular heart disease. The association between PH and ankylosing spondylitis (AS) is not so common and a few case reports have described a high incidence based on echocardiography but without right heart catheterization and no other connective tissue disease was excluded [13]. Only one case from 2022 has confirmed the diagnosis of PAH based on transthoracic echocardiography and right heart catheterization [14]. In conclusion, further studies are needed to establish a causal relationship between PH and ankylosing spondylitis.

Mixed connective tissue disease and PH. It is very difficult to estimate the exact prevalence of PH in mixed CTD because of the very frequent overlap syndromes where SSc may contribute to the high rates of PH [15]. The estimated prevalence is somewhere around 8%.

CLINICAL PRESENTATION

Patients usually present at first with non-specific signs and symptoms such as fatigue, weakness, dyspnoea on exertion, and dizziness and are usually described to appear due to connective tissue diseases per se. Other symptoms such as syncope, angina, ankle edema, and abdominal distention appear only after the vasculopathy has advanced and are signs of right heart failure [3].

PH associated with left heart disease (type 2 of PH) may be present among patients with SSc since cardiac dysfunction can develop in more than 40% of patients with SSc leading to myocardial and conduction system fibrosis which determines arrhythmias and diastolic heart failure. Atherosclerotic coronary vessel disease and hypertensive crisis may also appear.

More often, interstitial lung disease (ILD) can be present as a complication of SSc (SSc-ILD) leading to PH in 31% of cases. It is associated with the diffuse cutaneous form of SSc and the presence of positive Scl-70 (anti-topoisomerase) antibodies. Although these antibodies seem to have a protective role against PAH, type 3 PH may still appear due to interstitial lung disease [6].

DIAGNOSIS

Screening procedures. Early diagnosis is essential to improve survival in PAH patients. Therefore, early screening for diagnosis leads to adequate treatment at the right moment. The proper screening for PAH in SSc with a disease duration of more than 3 years and a modified DLCO (diffusion capacity of the lung for carbon monoxide) value is by using the DETECT algorithm based on non-invasive clinical and laboratory tests in order to reduce the missed diagnosis of PAH. Among patients with concomitant pulmonary emphysema, the utility of lung function tests is reduced as it might increase FVC (forced vital capacity) and diminish DLCO. The DETECT algorithm is based on 2 steps diagnosis: in step 1 clinical status, laboratory findings, and lung function tests (FVC, telangiectasia, anticentromere antibody positivity, electrocardiogram right axis deviation, and serum levels of Nt-proBNP and urate) should be determined and based on the results, echocardiographic parameters might be recommended in the second step to generate a final score. Based on the results of these steps, a right heart catheterization might be performed. The sensitivity of this method is high (96%) but it has a low specificity for detecting PH in SSc patients (48%). Screening for PH should be performed at least once a year. For other CTDs, there is no current systematic screening for PAH because of its low prevalence, although careful monitoring of these patients is recommended [8,10].

Biomarkers such as NT-proBNP and uric acid, which reflect cardiac dysfunction, are used in the DETECT algorithm as part of a screening method for PAH in SSc patients or other CTDs although these are not specific. One study identified other circulating biomarkers that might have a future impact on the diagnosis of PH and reduce the necessity of invasive procedures. Besides NT-proBNP, other proteins such as collagen IV, endostatin, insulin-like growth factor binding protein (IGFBP)-2, IGFBP-7, matrix metallopeptidase-2, neuropilin-1 and RAGE (receptor for advanced glycation end products) could improve the DETECT algorithm for screening of PH and understanding of different mechanisms in the pathogenesis of PAH. These markers are known to be involved in the process of pulmonary vascular remodeling, angiogenesis, and cellular growth but further data is needed in order to establish the exact role of these markers in PH [16].

Spirometry with DLCO estimation is important to evaluate the state of pulmonary function since DLCO is reduced in PAH (<50%) but FVC has a normal value and they have a high specificity (90%) and a high positive predictive value for SSc-PAH. In pulmonary fibrosis, both parameters are low [10]. This occurs due to a low blood volume in the pulmonary capillary in PAH patients and a diminution in the transfer capacity of the alveolar-capillary membrane. The best screening method for PAH among lung function tests is the FVC (% predicted)/DLCO (% predicted) [17].

Autoantibodies: Several SSc-specific antibodies are thought to be associated with PAH such as high anti-centromere ab (ACA) titers and some of the ANA panel. One study reported a significant correlation between SSc-PAH and the positivity of anti-U1-RNP and Th/To antibodies. Although AECAs (anti-endothelial cell antibodies) are involved in the vascular pathology of SSc further data is needed to demonstrate the exact implications of these antibodies in SSc-PAH. Another study reported the presence of anti-endothelin receptor type A antibodies (ETAR) and anti-angiotensin receptor type I antibodies (AT1R) as being the main factor of pulmonary vascular inflammation. The level of these antibodies was higher in the SSc-PAH patients compared to other forms of PH.

Transthoracic echocardiography (TTE) is recommended in all SSc patients once a year and it is the most common tool for screening SSc-PAH although it has a low predictive value [10]. There are many parameters that can be modified on TTE in case of PH: 1. right ventricle/left ventricle basal diameter ratio >1.0 or flattening of the interventricular septum; 2. early diastolic pulmonary regurgitation velocity >2.2 m/sec or increase in the tricuspid regurgitant jet velocity (TRV) and/or systolic pulmonary artery pressures (sPAP) and/or pulmonary artery diameter > 25mm; 3. inferior cava diameter >21 mm with decreased inspiratory collapse (18 cm) [17, 18].

Right Heart Catheterization (RCH): with the help of this procedure the diagnosis of PAH is established with certainty and the measurements that can be performed are the mPAP and the pulmonary capillary wedge pressure (PCWP), PVR, right atrium (RA) volume, and transpulmonary pressure gradient (TPG), by using a catheter inserted into the right femoral vein. RHC is the most precise method for the diagnosis of PH and it can offer information about the severity of the disease and prognosis. RHC is necessary when there is a moderate or high risk of developing PH based on the results of TTE [10,19].

TREATMENT

Because pulmonary hypertension due to autoimmune disease is a relatively rare syndrome and because it is challenging to treat, patients are probably best served if they are referred to a center that has experience with treating pulmonary hypertension. Close communication should be maintained between the referring physician and the treating physician [20].

No standard guidelines exist for the treatment of pulmonary hypertension associated with connective tissue disease.

Treatment recommendations, however, are modeled from the available literature on patients with PPH for several reasons. First, the clinical presentations and histopathologic features of PPH and autoimmune disease–associated pulmonary hypertension may be quite similar. Second, some patients who are initially diagnosed with PPH later manifest symptoms and signs of systemic autoimmune disease [21]. A further link between PPH and collagen-vascular disease–associated pulmonary hypertension is suggested by Isern et al, who found that 9 of 31 patients (29%) with PPH had specific autoantibodies associated with connective tissue diseases and 39% had Raynaud's phenomenon or positive antinuclear antibody results. Anti-Ku antibodies were found in 23% of patients with PPH [22]. Although the outcome still remains poor, many advances have been made in the last 30 years in vasodilator therapy, supportive care, and, more recently, the use of lung transplantation. These advances have improved survival and quality of life for PPH patients to a considerable extent. Further study of these therapies' usefulness among patients with pulmonary hypertension associated with systemic autoimmune disease is forthcoming.

General Supportive Therapy

The treatment of pulmonary hypertension should begin with the reversal of any contributing factors, including hypoxemia, hypercarbia, and acidosis. Such treatment is intended to reduce right heart strain with hopes of increasing survival. Oxygen supplementation to maintain arterial oxygen tension above 60 mm Hg or oxyhemoglobin saturation over 90% reduces mortality from cor pulmonale and improves cognitive function and quality of life in patients with the severe chronic obstructive pulmonary disease [23,24,25]. Others have shown that in primary pulmonary hypertension, low arterial oxygen saturation is the single best predictor of poor survival, as it is associated with a higher incidence of sudden death.

Digitalis, diuretics, and sodium restriction should be considered when heart failure persists. Although the use of digitalis in right-heart failure has been controversial and the drug is known to increase pulmonary vascular resistance and has a high incidence of toxicity in patients with cor pulmonale, it is shown to improve right heart function when left heart failure is also present, and it may offset the negative inotropic effects of calcium-channel blockers when they are administered concomitantly. Diuretics are useful in improving peripheral edema and hepatic congestion. Cautious administration is warranted, because it may lead to metabolic alkalosis, which, in patients with derangements in ventilatory control, may depress ventilatory response to carbon dioxide and lead to hypercarbia. Aggressive diuresis may also reduce right ventricular blood volume and reduce cardiac output. Finally, blood viscosity may increase due to a rise in hematocrit associated with diuresis. Serial phlebotomy may be required to decrease blood volume and viscosity in patients who have polycythemia associated with cor pulmonale.

Anticoagulation has been shown to provide survival benefits in patients with PPH. In situ, thrombosis due to endothelial injury and venous stasis and, sometimes, due to the presence of anticardiolipin antibodies may contribute to pulmonary hypertension in some patients by reducing the cross-sectional area of the pulmonary vascular bed [26]. In situ, thrombosis in pulmonary vessels has been shown to occur in all forms of pulmonary hypertension. Moreover, right heart failure, by promoting venous stasis, may further increase the risk of pulmonary thromboembolism. As such, anticoagulation with warfarin or with adjusted-dose or low-molecular-weight subcutaneous heparin in patients at risk for bleeding may benefit patients with pulmonary hypertension resulting from systemic autoimmune disease. Alternatively, the use of antiplatelet drugs such as aspirin or dipyridamole may be helpful; this recommendation is based on the fact that levels of urinary thromboxane A2, indicating platelet activation, are increased in some patients with pulmonary hypertension. Speculation exists that the beneficial effects of chronic prostacyclin infusion in some patients with in situ thrombosis may occur because of its potent anti-platelet aggregating activity rather than through vasodilatation because improved outcomes are seen even in patients who do not experience substantial acute hemodynamic changes. The same theoretic supposition applies to the suspicion that heparin may be preferred to warfarin because it inhibits smooth muscle and endothelial cell proliferation. The risk of anticoagulation must be considered, particularly because more than half of all patients with severe pulmonary hypertension experience syncope, and 15% experience hemoptysis [27].

Vasodilators

Vasodilator therapy has been used for more than 30 years in patients with PPH under the premise that pulmonary vasoconstriction, at least in part, contributes to the pathogenesis of this disease. Although it is not clear whether the vasoconstriction is the primary cause of increased pulmonary vascular resistance or results from distension of pulmonary blood vessels by increased intraluminal pressures, the premise also exists that even a small reduction in right ventricular afterload leads to clinically significant increases in right ventricular output. Not all patients will respond to vasodilators, and trials of vasodilator therapy are indicated to distinguish those patients who have a reversible vasoconstrictive component of pulmonary hypertension from those who have fixed pulmonary hypertension. While we await the results of a forthcoming prospective trial investigating the use of long-term therapy with prostacyclin among patients with pulmonary hypertension from systemic autoimmune disease, we include a discussion of vasodilator therapy for two reasons: first, some patients diagnosed with PPH later will manifest specific evidence for systemic autoimmune disease; and second, some patients with autoimmune disease–associated pulmonary hypertension have histopathologic changes on lung biopsy that are identical to those of PPH. As such, the two forms of pulmonary hypertension may, in fact, represent different points along the same continuum of disease progression, or may represent a common final pathway of injury following some inciting stimulus. The optimal response of vasodilator therapy is a reduction in PA pressure without a change in pulmonary capillary wedge pressure, along with an increase in cardiac output and thus a decrease in pulmonary vascular resistance. These changes should occur without a decrease in systemic arterial pressure or oxygenation. Only 15% to 30% of patients will experience such a response, however [28].

A second pattern is exhibited by approximately half of all patients with PPH, who experience a reduction in pulmonary vascular resistance in association with an increase in cardiac output, without a change in PA pressure. Although these patients also have increased exercise tolerance and improved right ventricular function, the duration of these improvements is unknown, as is the presence of any long-term survival advantage. In some patients, these hemodynamic improvements are most pronounced during exercise rather than rest, and so clinical benefits may exceed those predicted by responses measured during the resting state. The remaining quarter of patients are those in whom vasodilator therapy is contraindicated: they suffer a reduction in systemic blood pressure with acute vasodilator challenge, whereas PA pressure and cardiac output remain unchanged or increase. In these patients, vasodilators affect the systemic vasculature more than they do the pulmonary vessels. In response to the decrease in systemic vascular resistance, cardiac output may increase or remain unchanged. If cardiac output increases in response to systemic vasodilation, the increased flow through the pulmonary vessels will achieve the undesirable effect of a further increase in PA pressure. If the cardiac output does not respond to systemic vasodilation, then systemic hypotension will result, and this outcome may be resistant to most therapies, including discontinuation of the vasodilator. Volume resuscitation is often not helpful, and vasopressors may worsen pulmonary hypertension and increase right ventricular afterload. Such systemic hypotension may also precipitate acute angina or heart failure. The patients who experience a reduction in systemic blood pressure without reduction in PA pressure on acute vasodilator challenge are classified as having fixed vascular disease. Many drugs have been used to evaluate pulmonary vascular responsiveness [28]. The ideal drug, however, is one that: (1) elicits pulmonary vasodilation at a dose that has little or no effect on the systemic circulation; (2) is short-acting and is rapidly cleared from the circulation, so that baseline hemodynamics are reestablished soon after the drug is discontinued; (3) is easy to administer accurately in an incremental dosing regimen; (4) has hemodynamic and other side effects that accurately predict the response to longer-acting agents; and (5) is able to identify those patients who will not respond to therapy. In summary, a screening agent must be able to accurately reproduce the risk-benefit profile a patient will experience with longer-acting agents. This means identifying patients who will benefit from further trials with long-acting agents, as well as delineating those who should be spared from further therapeutic trials because of potential adverse outcomes of therapy.

Several agents have been used for screening: prostacyclin and its analog iloprost, acetylcholine, adenosine, and nitric oxide. Nitric oxide is administered by the inhaled route, whereas the others are given intravenously. The most intensively studied of these agents is prostacyclin, a metabolite of arachidonic acid produced by endothelial cells. Although it has some effect on systemic vascular resistance, it has almost all of the properties of an ideal screening agent. Its half-life is only 2 to 3 minutes, it has a rapid onset of action, its effects resolve rapidly after it is discontinued, and it is amenable to incremental intravenous dosing. Acute administration of prostacyclin has been shown to predict pulmonary vasodilator response to traditional long-term agents and identify those patients with PPH in whom long-term therapy may not be useful [29].

The recent approval by the Food and Drug Administration (FDA) for continuous long-term intravenous infusion in primary pulmonary hypertension has resulted in increased use of this drug as an alternative to traditional oral medications in selected patients [29]. Iloprost is a short-acting, stable carbocyclic derivative of prostacyclin with a longer half-life of more than 10 minutes. It has similar pharmacologic effects on the pulmonary circulation of patients with PPH. Recently, it has been used in long-term therapy for patients with pulmonary hypertension in the setting of connective tissue diseases. Acetylcholine is also short-acting and well-tolerated but may be a less potent vasodilator than prostacyclin, although this observation may in part be explained by the use of lower doses of acetylcholine [30]. Adenosine is a very short-acting pulmonary vasodilator, with a half-life of less than 10 seconds. It has been shown to have acute hemodynamic effects similar to those of prostacyclin in PPH [31].

Inhaled nitric oxide has selective pulmonary vasodilatory properties, with little effect on systemic circulation. It has an interesting additional effect of reducing intrapulmonary shunt and increasing systemic arterial oxygen saturation.

Transplantation

Transplantation has generally been reserved for those patients whose symptoms progress despite aggressive medical management, and who have New York Heart Association functional class III or IV heart failure [32]. The presence of severe right-sided heart failure that is accompanied by hepatomegaly, hyperbilirubinemia, and ascites confers high mortality, however, and these patients are not suitable candidates for transplantation. Transplantation has received attention in the recent past as a potential panacea for patients with severe forms of pulmonary hypertension, as it produced a dramatic reduction in PA pressure and reversal of right heart failure [33]. As experience has accrued, however, many centers have found that the incidence of acute complications following lung transplantation is greater among patients with systemic autoimmune disease than those with PPH, and some have abandoned it as a therapeutic option. Moreover, the incidence of postoperative Raynaud's phenomenon may be higher in these patients, and the vasoconstrictive effects of cyclosporine, which is used in posttransplant immunosuppression, are evoked as a putative mechanism. Other potential complications include bronchiolitis obliterans, which occurs with an incidence of 25% to 40%, and opportunistic infection [34,35]. Other limitations of transplantation include its confinement to certain specialized centers, its expense, and, regrettably, the paucity of donor organs [36]. Treatment of underlying systemic autoimmune disease

When pulmonary hypertension occurs in the setting of significant parenchymal lung involvement with systemic autoimmune disease, or due to vasculitis, the response to therapies targeted toward the underlying autoimmune disorder has been variable [37,38,39]. Small-scale studies suggest that traditional vasodilators alone may be ineffective. Most patients do not respond to corticosteroids, but some may [39]. In one series of three patients who had pulmonary hypertension in the setting of vasculitis, pneumonitis, and thrombosis, an aggressive combination of corticosteroids, anticoagulation, and either cyclophosphamide or azathioprine appeared to be beneficial [40]. In patients with rheumatoid arthritis who exhibit pulmonary hypertension because of pulmonary arteritis, which is thought to be due to deposition of immune complexes in vessel walls, the use of high-dose corticosteroids or cytotoxic agents has been investigated. Evidence has been unclear on whether such therapy improves overall outcomes.

Calcium-Channel Blockers

Although there is a paucity of data regarding their use in autoimmune disease–associated pulmonary hypertension, nifedipine, verapamil, diltiazem, and recently, nicardipine have been used against PPH. They are thought to act by reducing calcium influx into pulmonary vascular smooth muscle cells, thereby blocking muscle contraction and promoting vasodilation. Nifedipine is the most frequently used of the four, although nicardipine and diltiazem are useful when adverse effects of nifedipine occur. Among 10 patients with diffuse systemic sclerosis, CREST syndrome, or mixed connective tissue disease, oral nifedipine has been shown to produce both acute and chronic reduction (at 3 to 6 months) in pulmonary vascular resistance [41].

Prostaglandins

Prostacyclin is now FDA-approved for continuous intravenous infusion for the treatment of PPH, and may soon be routinely used for pulmonary hypertension associated with collagen vascular disease if results of a proposed clinical trial show therapeutic efficacy in this setting. Although it was initially proposed for patients who had severe forms of pulmonary hypertension as a bridge to transplantation, it has since been continued in patients who exhibit pronounced response to prostacyclin (PGI2) infusion, for a duration exceeding 5 years, with consideration for transplantation only if symptoms recur or if complications occur. The drug must be delivered by an infusion pump through an indwelling central venous catheter. Frequent dosing increments are required to maintain responses; moreover, complications including death have occurred because of failures in the drug delivery system, including thrombosis or infection of the catheter, pump malfunction, or interruption in the infusion system due to accidental disconnection. Nevertheless, studies have shown that long-term prostacyclin infusion offers symptomatic and hemodynamic improvement [42,43] and confers a survival advantage in advanced PPH [44,45].

Iloprost is a stable prostacyclin analog that has been studied in a number of settings. In the acute situation, high doses have been shown to reduce pulmonary vascular resistance in healthy persons, patients with PPH, and those with toxic oil syndrome, which results from ingestion of contaminated rapeseed oil and resembles scleroderma. Recently, de la Mata et al have studied the effects of long-term iloprost treatment in patients with severe pulmonary hypertension due to systemic sclerosis and primary antiphospholipid syndrome. They followed prospectively three patients with systemic sclerosis and two with antiphospholipid syndrome who did not respond to oral vasodilator therapy for pulmonary hypertension. They found that acute infusion of maximum tolerated doses reduced pulmonary vascular resistance and raised cardiac index and pulmonary arterial oxygen saturation in a statistically significant manner. After 32 weeks, all patients had improved exercise tolerance and New York Heart Association functional class. This improvement in exercise tolerance, however, was not accompanied by improvements in resting hemodynamics nor in pulmonary oxygen saturation, and one patient died. Further studies are needed to determine whether iloprost is more beneficial for patients who have less severe degrees of pulmonary hypertension than those in this study. In addition, long-term intravenous therapy continues to pose problems associated with the drug delivery system—one patient in this study died of bacteremia [30].

Oral iloprost has also been studied as a potential long-term therapeutic alternative to intravenous administration. In a European multicenter, double-blind, placebo-controlled trial of 63 patients with Raynaud's phenomenon, iloprost given orally at the maximum tolerated dose for 10 days resulted in reduced duration and severity of attacks of vasospasm. The results did not reach statistical significance, however, and this study did not include any assessment of the effects of this therapy on pulmonary vascular disease [46].

CONCLUSION

PH can be caused by several conditions in patients with systemic sclerosis or other CTDs and it is an important cause of mortality and morbidity, therefore early diagnosis and annual screening in asymptomatic patients is mandatory in order to provide adequate treatment. Even though significant efforts are being made regarding treatment options, long-term survival remains an important issue. The mortality rate of PAH in SSc patients is worse than the one in idiopathic PH and other CTDs due to a lack of response to treatment and the severity of the disease. More studies are needed in order to see progress in elucidating the pathogenesis and treatment regimens, especially the immunosuppressive therapy, and new non-invasive tools are required to simplify the diagnosis of PH and therefore improve patients' survival rate and quality of life [18,47].

Abstract: *Background: Pheochromocytomas (Pheo) are rare neuroendocrine tumors with a suggestive clinical picture, characterized by hypersecretion of catecholamines and other neuroendocrine biomarkers. Methods: The purpose of the study was to analyze the diagnostic features of Pheo and investigate the role played by different neuroendocrine and hormonal markers in diagnosing Pheo.The retrospective study involved a group of 69 patients diagnosed and treated with Pheo, who had both urinary and plasma catecholamines and neuroendocrine markers measured pre- and postoperatively. Results: After comparing pre- and postoperative hormonal parameters and neuroendocrine biomarker changes, numerous statistically significant findings were found. The analysis of the relationships between chromogranin A (CgA) levels, plasma and urine metanephrines, and normetanephrine and Pheo tumor size was included in the study. Additionally, we evaluated Cg A's diagnostic efficacy in comparison to plasma metanephrines, normetanephrine, and neuron-specific enolase (NSE) for Pheo. Conclusions: We obtained statistically significant data on pre- and postoperative differences for plasma and urinary catecholamines, CgA and NSE. Pheo tumor size is interdependent with serum levels of Cg A, plasma and urinary metanephrines, and normetanephrine. The best diagnostic power for Pheo was plasma normetanephrine, followed by plasma metanephrines and CgA.*

Keywords: *pheochromocytomas, catecholamines, chromogranin A, neuron-specific enolase*

INTRODUCTION

The term "neuroendocrine tumors" (NETs) refers to a wide range of extremely rare neoplasms that fall under the category of borderline endocrinology. They have the capacity to secrete a wide variety of physiologically active peptides and amines, which may result in a variety of biological behaviors and, in turn, metabolic and systemic consequences.

Advances in genetic studies have had a major impact in characterizing the hereditary aetiopathogenesis of pheochromocytomas (Pheo). In the 2000s years, it was thought that only 10% of these tumors, were recognized with a genetic cause, but now more than 18 genes have been described, whose mutations lead to the development of these tumor types in more than 30-40% of cases. In addition, large-scale studies target the genetic fingerprint of these tumor types as a possible pathophysiological key to further developing personalized medical therapy [1].

Currently, Pheo is defined as a catecholamine-secreting tumor originating from neuroendocrine chromaffin cells of the adrenal gland. In terms of pathophysiological mechanisms, Pheo can synthesize, store, secrete and metabolize catecholamines (noradrenaline and adrenaline, respectively their metabolites normetanephrine and metanephrine), thanks to their enzymatic background, namely tyrosine hydroxylase and dopamine β-hydroxylase enzymes. These two enzymes are found in both the adrenal medulla and sympathetic nerve ganglia and are responsible for the production of catecholamines and their storage in dense secretory vesicles together with CgA, adenosine triphosphate, calcium, magnesium, adrenomedullin, and other neuropeptides. CgA was first described as originating from adrenal chromaffin cells. It is a member of the granin family together with chromogranin B, chromogranin C (secretogranin II), secretogranins III-VI and vascular endothelial growth factor (VEGF) and it is considered a pro-hormone that plays multiple biological roles, including calcium homeostasis and mediating the secretion of catecholamines and other hormones [2-4].

In addition, the adrenal medulla is uniquely capable of producing and secreting adrenaline (epinephrine) and its metabolite metanephrine, thanks to a specific glucocorticoid-dependent enzyme of its own called phenylethanolamineN-methyltransferase (PNMT), which converts noradrenaline (norepinephrine) to adrenaline by methylation [5,6].

Pheo is characterized by clinical signs and symptoms specific to catecholamine hypersecretion (paroxysmal hypertensive crisis, diaphoresis, palpitations, headache, weight loss, hyperglycemia, etc.). Moreover, for Pheo, the clinical picture may include the specific classic triad: headache, sweating, and palpitations. However, non-specific symptoms may also occur, such as anxiety, weight loss, insomnia, or life-threatening cardiovascular events: rupture of an aortic aneurysm or stroke during a hypertensive crisis, hypertensive encephalopathy, catecholamine cardiomyopathy, etc [7].

The general biochemical diagnosis of catecholamines secreting NETs is characterized by the determination of specific markers: catecholamines and their plasmatic and urinary metabolites, chromogranin A (CgA), neuron-specific enolase (NSE) as well as by identifying the immunohistochemical expression of synaptophysin, CgA, etc. [8].

Serum CgA dosing and monitoring in Pheo is a topic of great interest in the literature and is currently included in current diagnostic and treatment guidelines. According to the body's literature, CgA levels are correlating with tumor volume, disease recurrence, and the presence of secondary determinations, especially hepatic [9,10].

MATERIALS AND METHODS

The aim of the study was to analyze the diagnostic features of Pheo and to identify possible correlations between various clinical and hormonal factors with an impact on clinical outcome and prognosis. Subjects were diagnosed with Pheo based on the following data:

- Suggestive symptomatology (hypertensive crisis, palpitations, sweating, headache, weight loss)

- Values that exceeded the upper limit of the reference range of plasma or urinary metanephrines and normetanephrine at least four times were considered diagnostic values

- Identification and localization of adrenal tumors by imaging techniques

- Pathological examination confirmed the diagnosis of Pheo

The study involved data collection and inclusion of 69 patients evaluated, diagnosed, and treated for Pheo of sporadic or genetic etiology. We investigated hormonal levels pre and post-operative, neuroendocrine biomarkers, and their correlations. According to the inclusion and diagnostic criteria, after obtaining informed consent, we enrolled in the study 69 patients with clinical suspicion of Pheo supported on the basis of biological and hormonal evidence, as well as on the basis of imaging investigations in whom histopathological examination obtained postoperatively confirmed the diagnosis. Clinical, biochemical, and hormonal parameters were monitored dynamically, i.e. preoperatively (at the time of diagnosis) and immediately postoperatively (at 2-4 weeks, the date of the first endocrinological evaluation after surgery). Our study included subjects evaluated and diagnosed in C.I. Parhon National Institute of Endocrinology Bucharest, during the period 2000-2017. We performed retrospective data collection of patients diagnosed and treated by Pheo from clinical observation sheets and electronic patient files. The collected data were entered into a database. Statistical interpretation of the data obtained was performed using IBM SPSS Statistics 20.0 and MedCalc 12. Results were expressed as mean ± standard deviation for numerical variables and as the frequency for categorical variables. The statistical tests used to interpret the data were the usual ones (minimum, maximum, mean, median values) as well as complex ones such as t-test (with the assumption of equal and unequal variances, respectively) for comparing the variance of means and F-test for comparing standard deviations. For statistical hypothesis testing, a p-value < 0.05 was used to assert a statistical correlation. The diagnostic power of the parameters was tested using the ROC curve.

RESULTS

Comparative analysis of pre- and postoperative hormonal parameters and neuroendocrine biomarkers changes for the Pheo group revealed numerous statistically significant data. The results of the statistical analysis of the dependent sample T-test, taking into account pre and postoperative values are reported in Table 1. Thus, in the Pheo study group, the mean plasma CgA level preoperatively was 390.43±173.83 ng/ml, and postoperatively it decreased statistically significantly ($p<0.001$) to 56.43±63 ng/ml. The NSE concentration also showed a statistically significant change ($p=0.004$) decreasing from a preoperative mean value of 12.98±1.69 ng/ml to 10.3±3.01. Plasma metanephrines recorded a mean value at diagnosis of 937.82±1201.51 pg/ml and decreased statistically significantly ($p<0.001$) postoperatively to 41.2±22.7 pg/ml. Plasma normetanephrine ranged from a preoperative mean value of 1712.11±1893.39 pg/ml to a postoperative mean value of 94.94±205.85 pg/ml, the difference being statistically significant ($p<0.001$). Regarding urinary metanephrines, they ranged from a mean value at diagnosis of 1798.81±2259.44 µg/24 hours to mean postoperative values of 96.1±80.9 µg/24 hours, reaching the threshold of statistical significance. Similarly, urinary normetanephrine had preoperative mean values of 3212.8±3284.07 µg/24 hours and postoperative mean values of 178±188.01 µg/24 hours, the difference being statistically significant (p<0.001, n=50).

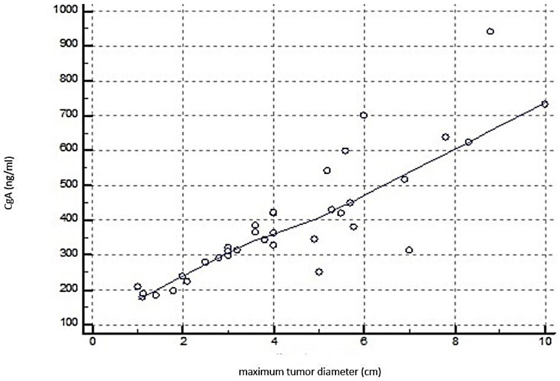
Table 1: T-test for paired samples – Evolution of pre- and postoperative parameters in the Pheo group.

Variable	Pheo		N	Sig.	Correlation	Mean Diff.	Sig (2 tailed)
	Preop. mean	Postop. mean					
CgA (ng/ml)	390.43±173.83	56.43±63	28	0.046	0.38	334±110.83	<0.001
NSE (ng/ml)	12.98±1.69	10.3±3.01	12	0.08	0.698	2.68±1.32	0.004
Plasma metanephrines (pg/ml)	937.82±1201.51	41.2±22.7	69	0.92	-0.12	896.62±1178.8	<0.001
Plasma normetanephrine (pg/ml)	1712.11±1893.39	94.94±205.85	69	0.017	0.286	1617.17±1687.5	<0.001
Urinary metanephrines (µg/24 ore)	1798.81±2259.44	96.1±80.9	52	0.218	0.151	1702.7±2178.54	<0.001
Urinary normetanephrine (µg/24 ore)	3212.8±3284.07	178±188.01	50	0.06	0.177	3034.8±3096.06	<0.001

We also statistically analyzed the correlations of CgA levels and plasma and urinary metanephrines and their metabolites with Pheo tumor size.

Regarding the correlation of preoperative serum Cg A levels with Pheo tumor size, the results of the statistical analysis showed a positive association, with high statistical significance (P<0.0001, r=0.86), being plotted in Figure 1.

Figure 1: Correlation of CgA and tumor size in the Pheo group



In addition, by studying the correlation of mean plasma metanephrines level with tumor size, we obtained a statistically significant positive correlation (P<0.0001, r=0.57), plotted in Figure 2.

In addition, serum plasma normetanephrine levels also showed statistically significant positive correlations with Pheo size (P=0.0002, r=0.43), plotted in Figure 3.

Similarly, regarding urinary metabolites of catecholamines, in Figure 4 it can be seen the presence of a positive association of urinary metanephrine level with Pheo maximum tumor diameter (P<0.0001, r=0.55).

In addition, urinary normetanephrine levels at the time of diagnosis showed a positive correlation as shown in Figure 5, with statistical significance (p<0.001, r=0.53).

Moreover, in terms of genetic or sporadic etiology in Pheo, the statistical data did not show a statistically significant difference (P=0.411, F-ratio=0.691) in plasma levels of Cg A. Thus, the mean serum CgA in genetic cases was 341.18±140.09 ng/ml (n=7), and in sporadic Pheo cases mean serum CgA was 402.32±181.15 ng/ml (n=29), without statistical significance.

Figure 2: Correlation of plasma metanephrines with tumor size in Pheo

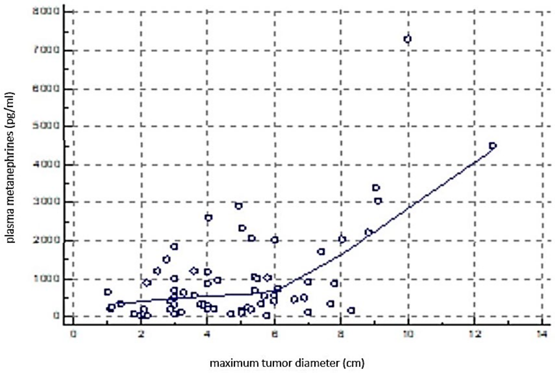


Figure 3: Correlation of plasma normetanephrine with tumor size in Pheo

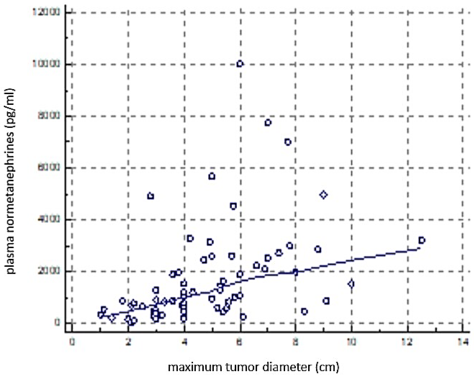

Figure 4: Correlation of urinary metanephrines with tumor size in Pheo

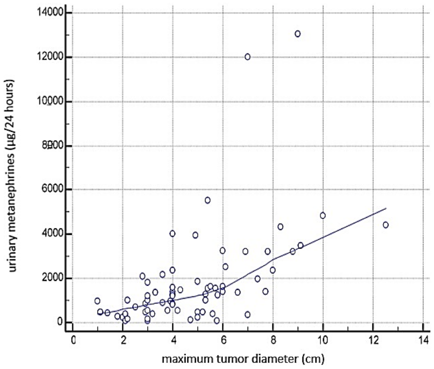

Figure 5: Correlation of urinary normetanephrine with tumor size in Pheo

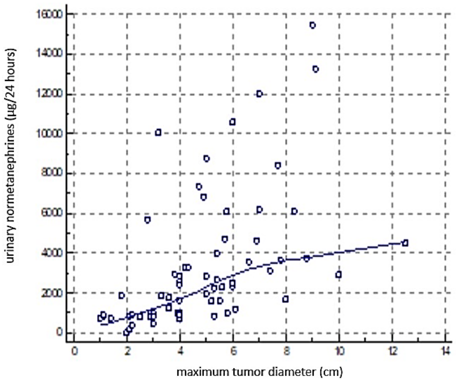
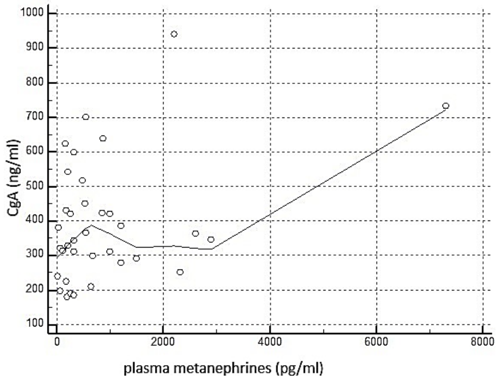


We also investigated correlations between CgA levels and hormone levels.

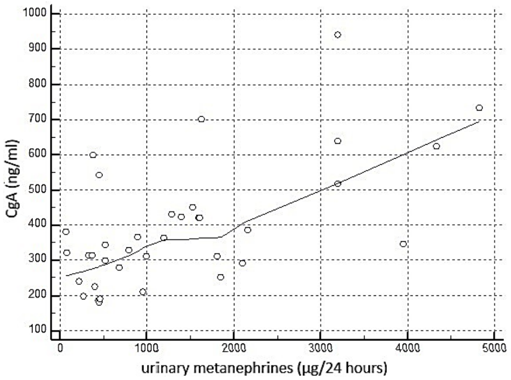
We identified a statistically significant positive correlation (p=0.02, r=0.37) between serum CgA and plasma metanephrine levels at the time of Pheo diagnosis, illustrated in Figure 6.

Figure 6: Correlation between preoperative plasma CgA and metanephrine levels in Pheo



Similarly, regarding the correlation of urinary metanephrine levels with serum Cg A concentration, there was a statistically significant positive correlation (P=0.0001, r=0.62), as shown in Figure 7.

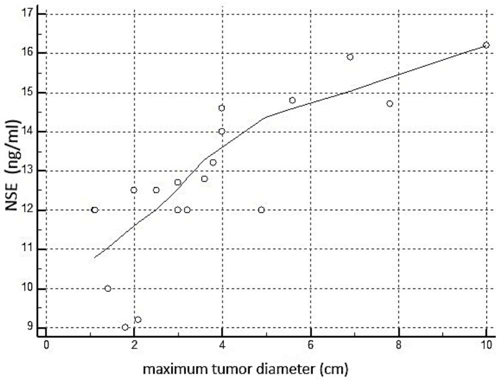
Figure 7: Correlation between serum CgA and preoperative urinary metanephrines in Pheo



In contrast, we did not obtain statistically significant data implying correlations between preoperative serum CgA and plasma normetanephrine levels (p=0.18, r=0.22) nor urinary normetanephrine (p=0.12, r=0.26).

Regarding the correlations between serum NSE level, we identified a preoperative mean value of 12.98±1.7 ng/ml (n=18) which correlated positively, statistically significantly (p<0.0001, r=0.76) with Pheo tumor size, being illustrated in Figure 8.

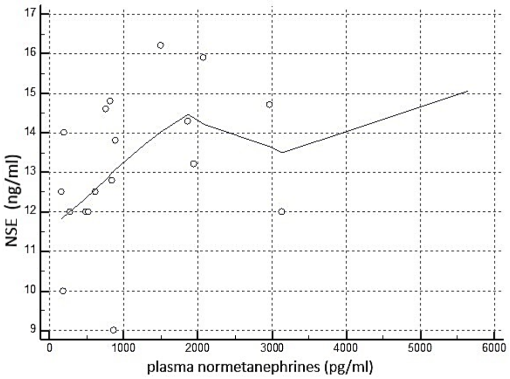
Figure 8: Correlation between tumor diameter and serum NSE level in Pheo



Similarly, we found no statistical significance for the correlation of serum NSE levels with plasma metanephrines at the time of Pheo diagnosis (p=0.10, r=0.35), urinary metanephrines (p=0.2, r=0.48) and urinary normetanephrine (p=0.23, r=0.26).

However, the correlation of preoperative serum NSE levels with plasma normetanephrine showed a positive line and was statistically significant (p=0.03, r=0.44), as shown in Figure 9.

Figure 9: Correlation of preoperative serum levels between serum NSE and plasma normetanephrine in Pheo

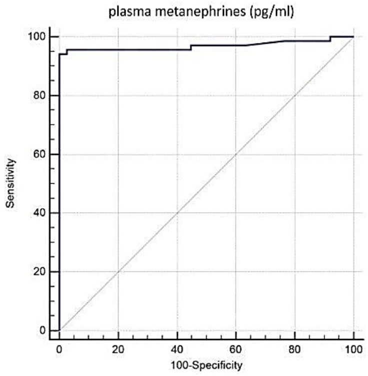


Regarding the analysis of NSE concentration according to Pheo etiopathogenesis, we found no statistically significant differences (p=0.74, r=1.332) between genetic Pheo whose mean serum NSE concentration was 12.75±1.19 ng/ml (n=4) and sporadic Peo whose mean NSE concentration was 13.06±2.22 ng/ml (n=14).

We performed also the analysis of the diagnostic power of Cg A versus plasma metanephrines and normetanephrine for Pheo.

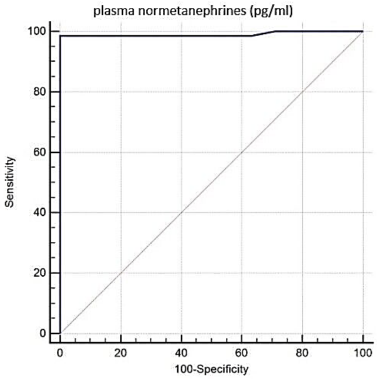
Regarding the sensitivity and specificity of plasma metanephrines for Pheo diagnosis, being plotted in Figure 10, the results of statistical analysis indicated that a plasma metanephrines cut-off value >58 pg/ml has a sensitivity of 94.2% and a specificity of 100% for Pheo diagnosis, being highly statistically significant (p<0.0001) and AUC=0.970.

Figure 10: Sensitivity and specificity of metanephrines in the diagnosis of Pheo



Similarly, analyzing the sensitivity and specificity of plasma normetanephrine for the diagnosis of Pheo, illustrated in Figure 11, the results indicated that a plasma normetanephrine cut-off value > 72 pg/ml has a sensitivity of 98.55% and a specificity of 100% for the diagnosis of Pheo, with high statistical significance (p<0.0001) and AUC=0.990.

Figure 11: Sensitivity and specificity of normetanephrine in the diagnosis of Pheo



Additionally, combining plasma metanephrines and normetanephrine as a diagnostic element, there are no statistically significant differences between the two ROC curves (p=0.31), suggesting statistically similar diagnostic power, as shown in Figure 12.

Figure 12: Sensitivity and specificity of metanephrines and normetanephrine in the diagnosis of Pheo

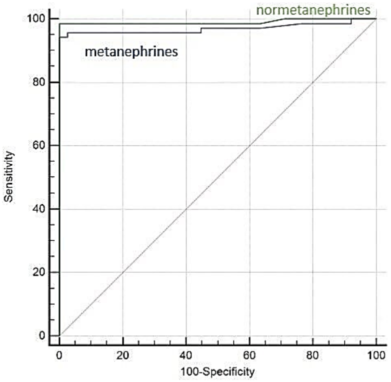


Figure 13: Sensitivity and specificity of CgA for the diagnosis of Pheo

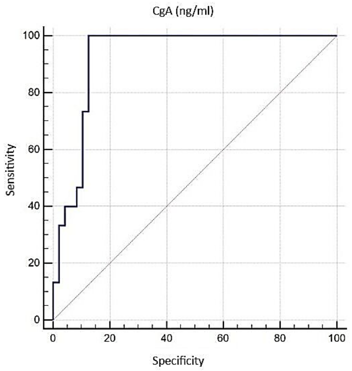
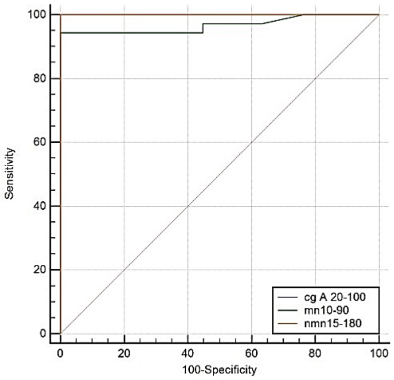


Analyzing the sensitivity and specificity of CgA for Pheo diagnosis, according to Figure 13, we obtained a sensitivity of 100% for cut-off values of CgA>197 ng/ml and a specificity of 87.5%, with high statistical significance (p<0.0001) and

AUC=0.926.

In Figure 14, it can be seen the sensitivity and specificity of CgA compared to that of plasma metanephrines and normetanephrine in the Pheo group at the time of diagnosis, but without a statistically significant difference (p=0.16, p=1) compared to the other two.

Figure 14: Sensitivity and specificity of plasma CgA, metanephrines, and normetanephrine in the diagnosis of Pheo



DISCUSSION

The biochemical diagnosis of Pheo is based on the determination of plasma and urinary metanephrines and normetanephrine and secondarily on the determination of neuroendocrine markers [11]. An important theme of our study was the dynamic (pre and postoperative) assessment of hormonal parameters. CgA is a glycoprotein that belongs to the granin family and Its dosing is recommended for the diagnosis and monitoring of NET [12]. Dynamic pre- and postoperative CgA assessment in Pheo was studied by others who reported a mean preoperative CgA ranging from 600- 632 ng/ml with a significant decrease postoperatively (p<0.001) [13-15]. Our data are consistent with the findings of the studies already mentioned, but the mean preoperative CgA value was 390.43±173.83 ng/ml, the difference may derive from different CgA assay methods (radioimmunoassay or ELISA technique), but the significant decrease postoperatively is conclusive. At the same time, the NSE dynamics recorded in our study (12.98±1.69 ng/ml preoperatively and 10.3±3.01 postoperatively) are within the literature studies [16]. Additionally, the course of plasma and urinary metanephrine and normetanephrine values showed significant decreases in the study, consistent with the data from the literature [17-19].

Analyzing the correlations between Pheo size and the amount of plasma and urinary metanephrines and normetanephrine, respectively neuroendocrine markers secreted at the time of diagnosis, we found statistically significant positive correlations for serum CgA levels (P<0. 0001, r=0.86), NSE (P<0.0001, r=0.76), as well as with plasma (P<0.0001, r=0.57); P=0.0002, r=0.4) and urinary (P<0.0001, r=0.55; p<0.001, r=0.5) metanephrines and normetanephrine levels. Our results correspond with data reported by the study of Unger N. et al. [18] which identified a positive correlation between CgA levels and tumor volume (p<0.001), as well as research of d'Herbomez et al. [20] that highlighted positive correlations between both preoperative CgA concentration and plasma and urinary fractional metanephrine levels with tumor volume. In contrast, the research of Guerrero M et al. [21] showed only a positive correlation between urinary normetanephrine levels with tumor size. In addition, similar to data confirmed in the literature, we obtained statistically significant data regarding positive correlations between preoperative CgA levels with plasma (p=0.02, r=0.37) and urinary (P=0.0001, r=0.62) metanephrines levels but we found no correlations with urinary and plasma normetanephrine. Similar to the study of Okamura T et al. [22] identified interdependence between CgA and urinary metanephrine levels (r= 0.80; P<0.0001), but as in our case, they did not reach the threshold of statistical significance for correlations of urinary and plasma normetanephrine with CgA.

Regarding the analysis of differences in biochemical parameters and genetic or sporadic etiopathogenesis of Pheo, we did not find statistically significant correlations for CgA (p=0.411, r=0.6) or NSE (p=0.74, r=0.1). In parallel, studies of Eisenhofer G et al. [23] and Zuber S et al. [24] reported a statistically significant difference in CgA values, whereas the research of d'Herbomez M et al. [14] reported a statistically insignificant difference (p=0.35) between CgA values between genetic and sporadic Pheo cases. We can assume that our data did not reach the threshold of statistical significance due to the small number of patients with Pheo of genetic cause in whom we had CgA and NSE assays available.

Regarding the sensitivity and specificity of plasma metanephrines for the diagnosis of Pheo, the results of our analysis indicated that a plasma metanephrine cut-off value >58 pg/ml has a sensitivity of 94.2% and a specificity of 100%, with AUC=0.970 for the diagnosis of Pheo. Similarly, the study of d'Herbomez M et al. [14] indicated a sensitivity of 71% and a specificity of 89.9%, and the study of Unger N et al. [18] indicated values of 70% respectively 90%, with AUC=0.8. Similarly, analyzing the sensitivity and specificity of plasma normetanephrine for Pheo diagnosis, our results indicated a sensitivity of 98.55% and a specificity of 100% for Pheo diagnosis, with AUC=0.990. Literature reports converge towards the same values, thus the study of d'Herbomez M et al. [14] reported a sensitivity of 95.2% and a specificity of 98.6% and the study of Unger N et al. [18] indicated a sensitivity of 89.5%, and a specificity of 98.3%, with AUC=0.91. Additionally, combining plasma metanephrines and normetanephrine as a diagnostic element, in our research we did not obtain statistically significant differences between the two ROC curves (p=0.31), suggesting statistically similar diagnostic power. Similarly, the research of Unger N et al. [18] reported a sensitivity of 89.5% and a specificity of 95% when combining the two diagnostic tests. Analyzing the sensitivity and specificity of CgA for Pheo diagnosis, we obtained a sensitivity of 100% and a specificity of 87.5%, with AUC=0.926. The study of Grossrubatscher E et al. [20] revealed a sensitivity of 91% and a specificity of 95% for CgA, while the study of d'Herbomez M et al. [14] reported a sensitivity of 98.3% and a specificity of 97% and the study of Unger N et al. [18] reported a sensitivity of 73.9% and a specificity of 74.2% with AUC=0.74.

CONCLUSIONS

We obtained statistically significant data on pre- and postoperative differences for the following hormonal and neuroendocrine parameters: CgA, plasma metanephrines and normetanephrine, urinary metanephrines, and normetanephrine. Pheo tumor sizes are interdependent with serum levels of Cg A, plasma and urinary metanephrines, and normetanephrine. In terms of inter-hormonal correlations, serum NSE levels correlate significantly with plasma normetanephrine levels and serum CgA levels correlate with plasma and urinary metanephrine levels. The best diagnostic power for Pheo was plasma normetanephrine (AUC=0.99), followed by plasma metanephrines (AUC=0.97) and CgA (AUC=0.92).

Abstract: *This is a narrative review based on published articles, using the following criteria: key words "ovarian dysgerminoma" and "MRI (Magnetic Resonance Imaging)"; PubMed access; full-length English articles since inception to May 2023; original studies and case reports/series. Exclusion criteria were ovarian tumors other than dysgerminomas, non-English papers, non-human studies, and reviews. Dysgerminomas are the most common ovarian malignant germ cell tumors, accounting for 1-2% of all primary ovarian neoplasms.*

Keywords: *dysgerminomas, germ cell tumor, malignant tumor, MRI*

INTRODUCTION

The frame of ovarian dysgerminoma

Up to one-third of all ovarian malignancies are represented by germ cell tumors, but only 5% of these are malignant [1,2].

Ovarian germ cell tumors include, as proposed in the 2020 World Health Organization Classification of Tumors, teratomas, mature or immature, dysgerminomas, yolk sac tumors, embryonal carcinoma, non-gestational chorio-carcinoma, mixed germ cell tumors, mono dermal teratomas, and germ cell-sex cord-stromal tumors [3].

Dysgerminomas are the most common ovarian malignant germ cell tumors, accounting for 1-2% of all primary ovarian neoplasms [4,5]. In 75% of the cases, they occur after the onset of puberty [4]. Key features are the lack of precursor lesions and of specific differentiation patterns [5], a less invasive behavior with a good prognosis after surgical treatment, with a nearly 100% 5-year survival [6,7,8] and almost 90% at 10 years [9,10,11].

Although the age range reported for ovarian dysgerminoma is 7 months to 70 years old, their peak incidence occurs after puberty, more specifically in the second and third decades of life [12].

They are believed to develop from primordial germ cells that present spontaneous transmembrane tyrosine kinase receptor c-kit (CD 117) mutations. These mutations are usually observed in unilateral dysgerminomas, probably occurring after the cellular migration to the gonadal ridges [13,14].

Histologically, ovarian dysgerminomas, considered the microscopical female correspondent of the male testicular seminomas and extragonadal germinoma, are composed of undifferentiated germ cells with well-defined cytoplasmic borders, large nuclei, numerous mitoses, and clear cytoplasm, who are typically arranged in sheets or elongated nests with a palisaded peripheral cell arrangement, frequently infiltrating the stroma. The gross appearance of a well-encapsulated solid mass with an average diameter of 15 cm, but there are 50 cm cases reported, with a grey-white or light tan fleshy lobe-like pattern on section [2,3,6,7,14,15].

Immunohistochemistry shows positive testing for CD117, thus correlating with KIT mutations, while positive expression of organic cation/carnitine transporter 4 (OCT 4), spalt-like transcription factor 4, and D2–40 can also be determined. 30% of the tumours are present with vimentin (+), lactate dehydrogenase -LDH (+) and neuronal specific enolase- NSE (+). Although these tumors are not hormone-producing, still, human chorionic gonadotrophin (hCG) and ihibin are found positive in syncytiotrophoblastic cells [2,5,6,16,17].

These tumors have a propensity for bilateral involvement, with up to 5-10 % of the cases presenting as bilateral ovarian masses [18].

Their management involves surgery, and, in stages beyond IA chemo- and or radiotherapy are added as a mandatory therapeutic step [19,20].

Since these patients are usually under 30 years old and there is a time frame of at least 5 years between the diagnosis and the conception moment, optimal preoperative diagnosis is mandatory, and fertility preservation surgery becomes a key issue in their management [13,19,21,22]. 15%–20% are diagnosed during pregnancy or post-childbirth and are the most frequent tumors in pregnancy [23].

Diagnostic workup includes imaging studies, such as transabdominal ultrasound (in children), a transvaginal ultrasound, computed tomography scan (CT scan), and magnetic resonance imaging (MRI) studies, along with serum markers assay for differential diagnosis of the abdominal mass. Flourine-18 fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) is not a usual diagnostic tool, but rather used for relapse, or follow-up after chemotherapy or surgery [24, 25, 26]. Dysgerminomas are associated with various elevated serum markers. Elevated LDH, alkaline phosphatase is frequently found in these patients' assays [27].

Despite the progress of ultrasound imaging and the introduction of IOTA criteria for distinguishing between benign and malignant lesions, up to 25% of the lesions remain indeterminate, requiring further imaging investigation [28].

Clinical presentation of these rapid-growth abdominal masses ranges from incidental findings on imaging studies to the more common abdominal enlargement, associated pain, or menstrual abnormalities. Precocious puberty, metrorrhagia, and acute abdomen due to tumor rupture, torsion, or hemorrhage are also noted.

Differential diagnosis includes but is not limited to other histological types of ovarian tumors (benign or malignant), ovarian metastases, or ovarian myomas.

Ovarian dysgerminoma complicated with torsion, rupture can mimic other acute abdominal conditions, such as acute appendicitis, diverticulitis, tubo-ovarian abscess, ectopic pregnancy, or ruptured follicular cyst [29].

According to NCCN (National Comprehensive Cancer Network) Guidelines 2020, in patients who desire to preserve fertility, fertility-sparing surgery following comprehensive surgical staging is mandatory and consists of unilateral salpingo-oophorectomy along with all visible tumors' resection [30,31].

MATERIALS AND METHODS

This is a narrative review based on published articles, using the following criteria: keywords "ovarian dysgerminoma" and "MRI"; PubMed access; full-length English articles since inception to May 2023; original studies and case reports/ series. Exclusion criteria were ovarian tumors other than dysgerminomas, non-English papers, non-human studies, and reviews.

According to our four main criteria, we identified 40 papers that we manually checked and excluded 3 papers, 1 veterinary study, and 2 articles in another language than English. We considered the various imaging aspects with consideration to the clinical practice (Figure 1).

Figure 1: Flowchart according to our methodology (n = number of articles).

RESULTS

Ultrasound features

Ultrasound features involve a well-defined, highly vascularized, heterogenous multilobulated solid mass with significantly vascularized septa [32].

MRI features

MRI aspects include intermediate signal intensity on T2-weighted imaging (T2WI) and high the lobulated aspect seen on ultrasound is also found on CT scans, with enhanced septa. Cystic areas represent either hemorrhage or necrosis. Speckled calcification can be found, especially in hypercalcemia patients. MRI scan shows a similar solid lobulated mass with fibrovascular septa, with low intensity on T1-weighted images (T1WI) and intermediate signal intensity on T2-weighted imaging (T2WI). They usually have high signal intensity on DW imaging and low ADC value. Fibrovascular septa are hyperintense on T2W1 in the presence of edema [32-34].

Zhao et al. divided septa into four categories, according to the degree of edema: Type I consists of thin non-oedematous hypointense T2W1 septa, which are unrecognizable on pre-contrast CT scans. Type II are thin T2W1 hyperintense oedematous septa. Type III are included thick oedematous T2W1 hyperintense septae with hypoattenuation in pre-contrast CT scan. Type IV consists of map-like T2W1 oedematous morphous septae that are usually found in large tumors [35].

Multiplicity can be found as small nodules with high signals on DWI. Large tumor vessels can be found at the center of the lesions with radiant peripheral distribution through the vascular septae. In a case series, the multiplicity detected in the MRI studies is considered to be most likely a sign of the transformation of gonadoblastoma to germinoma [32-36].

According to the same authors, the central vasculature found in MRI studies is most likely a typical finding of dysgerminoma, but further studies are required [36].

18F-FDG PET/CT

The role of 18F-FDG PET/CT is not currently set for ovarian malignant germ cell tumors; it is usually used for the restaging of residual disease after chemotherapy, after surgery, or follow-up in apparently disease-free patients. A negative 18FDG PET/CT might be useful to reduce the number of excessive invasive procedures [37].

In a case of a 21-year-old female with ultrasound evidence of a large solid mass in the abdomen and elevated CA-125, right large pleural effusion on CT-scan, the 18F-fluoro-2-deoxy-D-glucose positron emission tomography maximum standardized uptake was 15,8. Areas of tumor mass reduced metabolism were secondary to tumor necrosis [38].

Associated conditions

Ovarian dysgerminoma can be associated with various other conditions. Patients with disorders of sex development or dysgenic gonads can associate malignant transformation. There are reported cases of Turner syndrome, triple X syndrome, or testicular feminization [39,40].

Patients with disorders of sex development, such as 46, XY with SRY mutations in the high mobility group domain have an increased risk of ovarian malignant transformation, requiring specific investigations [39,40].

Demon Meigs syndrome, consisting of co-occurrence of an ovarian mass, pleural effusion, and elevated serum cancer antigen CA-125 levels, can associate with ovarian dysgerminoma. In the case of a 19-year-old patient presenting with dyspnea and fever, a large right pleural effusion, a small number of ascites, and a huge (29.2 cm × 11.8 cm × 8.4 cm) abdominopelvic tumor were diagnosed. Elevated serum markers- CA-125, LDH, ROMA score suggested the presence of a malignant ovarian mass. The surgical specimen- solid, fleshy, cream-colored, creatine kinase (+), leukocyte common antigen (lymphocyte, +), placental alkaline phosphatase (+), CD30 (−), CD117 (+), α-fetoprotein (−), podoplanin (+), human chorionic gonadotropin (HCG) (+), and inhibin-α (−) was confirmed as dysgerminoma [41, 42].

Unlike seminoma in males, the association of Down syndrome with ovarian dysgerminoma is rather unusual, with only five cases being reported so far in the literature. There is no proven link so far between the two conditions, but the possible association might be secondary to an effect of genetic overexpression, hormonal imbalance, and a higher affinity of the trisomic cells to carcinogens [41,42].

Pregnancy-associated dysgerminoma

Pregnancy-associated dysgerminoma is an extremely rare presentation, and according to a literature review, only 21 cases were published in the last 7 decades. The symptoms are similar to non-pregnant patients, ranging from no symptoms to abdominal distension, and growing abdominal mass. In 2 cases, obstructed labor was reported leading to tumor incarceration. The diagnosis was made based on ultrasound or MRI reports along with elevated serum tumor markers- LDH, the most sensitive, AFP or CA-125. In pregnant patients, MRI studies are second-line imaging tools, used only for confirmation/further investigation of the cases where ultrasound was not sufficient for diagnosis. Several complications can occur during vaginal delivery- incarceration or a caesarean section- tumor rupture. Fetal death can occur in up to one-quarter of the cases [43,44].

Lymph node metastasis

The metastatic pattern in advanced dysgerminoma was only reported isolated in several studies, although this tumor is more metastatic than other histological types of ovarian cancer. It is more likely to develop para-aortic lymph node metastasis than in other stations.

FDG PET CT might help in the identification of these metastatic lymph nodes, reducing the burden associated with extensive tumor relapse treatment. A case series of two patients who presented with an initial FIGO IA stage showed how an improper initial surgery might lead to inadequate assessment and staging of the tumor. The first patient received surgery and lymph node sampling (who was negative) and had a subsequent nodal relapse. The second patient was offered surgery without lymph node sampling/lymphadenectomy and thirteen months later she presented with a para-aortic tumor that required extensive surgery and treatment [45,46].

A case of cervical lymph node metastasis was confirmed by fine needle aspiration after 18FDG PET-CT in a 20-year-old woman who presented with a large abdominal mass and cervical swelling [47].

Rare associations

A case of ovarian dysgerminoma was reported in association with Mullerian agenesis, in a 20-year-old woman who presented with symptoms of pregnancy, and a positive urinary pregnancy test. Clinical and ultrasound evaluation showed the lack of a right ovary and uterus with a normal-appearing left ovary. She confirmed primary amenorrhea. Seriated pelvic MRI initially showed a 2 cm low T1 and low T2 signal mass adjacent to the normal-appearing right ovary, corresponding to a 3/1.5 cm solid pink smooth tumor invading the ovarian hilum. The pathology report confirmed a dysgerminoma containing syncytiotrophoblast cells and microscopic tumoral foci away from the main tumor. Immunohistochemistry was positive for placental alkaline phosphatase and weekly positive for beta HCG [48].

A unicornuate uterus, non-communicating rudimentary horn, and right homogenous mass- dysgerminoma, was reported in an 18 -year- old woman [49].

Ovarian dysgerminoma complications

Dysgerminoma usually presents rapid growth with subsequent torsion and rupture of hemorrhage. Patients present abdominal pain with a sudden increase in intensity, abdominal distension, and a palpable mass revealed on clinical examination. Loss of appetite, nausea, or vomiting can be associated. The size of the tumor determines the intensity and the rapidity of the onset of the symptoms. In such emergency cases diagnosis is usually based on ultrasound and CT-scan, MRI requiring a longer acquisition time. A CT scan might show an area of necrosis or edema with low attenuation, the presence of pelvic free fluid, and the twisted vascular pedicle originating from the adnexa [50,51].

An unusual case of aggressive systemic mastocytosis was reported in a 16-years-old female who was diagnosed with ovarian dysgerminoma 2 years before and received 4 cycles of neoadjuvant chemotherapy (bleomycin, etoposide, and cisplatin) followed by surgery and adjuvant carboplatin and etoposide, with normalization of alpha-fetoprotein levels. 2 years later she complained of bone pain, skin rash, fever, and anaphylaxis and imaging studies revealed spine osteosclerosis and osteolysis, yet no tumor mass was present. AFP levels were normal and immunohistochemistry staining was positive for mast cell tryptase, CD25, CD33, and c-KIT. The serum tryptase level was elevated. Her symptoms were alleviated with prednisolone, but significant improvement was achieved with tyrosine kinase inhibitor – nilotinib [52].

Hypercalcemia can be found in 5% of gynecologic neoplasms, including dysgerminoma, with clinical symptoms depending on the baseline general status, level of calcemia, or rapidity of progression [53]. Two-thirds of ovarian cancer associated with hypercalcemia can be found in small cell carcinoma of the ovary, dysgerminoma being the second associated most common pediatric ovarian malignancy. Fifteen cases of dysgerminoma-associated hypercalcemia have been reported so far. Symptoms include the presence of tumoral mass, abdominal pain/distension, unintentional weight loss, dyspnoea on exertion, nausea constipation, lethargy, polydipsia, and polyuria [54].

Unlike hypercalcemia associated with breast cancer, where a local osteolytic mechanism is involved, in ovarian cancer associated with hypercalcemia, a systemic secretion of parathormone-related peptide (PTHrP) is the cause of the humoral abnormality. Abnormal tumoral expression of 1-alpha-hydroxylase can also be incriminated. 1,25 dihydroxy vitamin D might be involved in malignant-associated hypercalcemia by increasing both osteoclastic bone resorption and intestinal calcium absorption. Surgery is usually followed by the resolution of the symptoms [55,56].

DISCUSSION

Ovarian dysgerminoma is a rare malignant ovarian tumor, diagnosed in the first three decades of life, with a favorable prognosis if the appropriate treatment is given. According to FIGO staging, the initial treatment can either be surgery or neoadjuvant chemotherapy. Since patients are very young, fertility preservation is a major concern and current surgical options include fertility-sparing techniques [13,19,30,31,57].

Due to the scarcity of the literature data, imaging criteria are not very clear. The ultrasound IOTA criteria were introduced to distinguish between benign and malignant ovarian masses [28,31]. Additional imaging studies are further required in possible malignant tumors. CT scan is more likely to be used in emergency situations including acute abdomen due to rupture, hemorrhage, or ovarian torsion. In such cases, an MRI examination would be a time-consuming investigation and doesn’t really add supplementary information. Regarding the evaluation of lymph node status, both CT scan and MRI can give information on para-aortic nodes, as these are the most frequent metastatic site. 18FDG PET-CT might be helpful in identifying the metabolically active areas (lymph node stations) that should undergo surgery [37,38]. MRI studies are valuable for the evaluation of ovarian tissue and vascularization and can add important data on other abnormalities, such as disorders of sex development, and other associated soft tissue anomalies [39,40].

There are two specific aspects that are described in MRI scans. The first one, the multiplicity defined as the presence of small nodules that can be found in section studies, is indicative of early stages or slow-growing tumors. The central vascular vessels, the second characteristic, also seems to be kind of specific for these tumors, as it is usually not described in other histological types of ovarian malignancies, but further studies are required.

Considering the possibility of ovarian dysgerminoma-associated hypercalcemia, the measurement of serum levels of PTH, PTHrP, and 1,25-hydroxyvitamin D seem to be useful, as neurocognitive dysfunction, volume depletion, and renal failure might prove to be serious complications.

Given the reviewed data, the management algorithm in ovarian dysgerminoma patients should include several mandatory aspects. A careful history of all the symptoms is the first step in the evaluation of the patient, followed by ultrasound, abdominal or transvaginal. Serum markers assessment along with supplementary investigations, such as upper and lower GI endoscopy, and cystoscopy can be used in selected cases. A thorough description of the lesion, of the lymph nodes, and the evaluation of possible complications can be achieved through imaging studies – chest X-Ray for pleural effusions, CT/MR scan, and 18FDG PET-CT if available for lymph node evaluation. Neoadjuvant chemotherapy can be used in advanced metastatic disease, followed by surgery. According to current guidelines for non-epithelial ovarian tumors, in the early stages, initial minimally invasive fertility-sparing surgery is the treatment of choice [58,59].

Although ovarian dysgerminoma has a good prognosis with appropriate treatment, optimal diagnostic work-up is mandatory to achieve the best results in young women.

Abstract: *Chronic inflammation and immunosuppressive treatment may play a role in the etiopathogenesis of cancer in psoriasis patients. We wanted to evaluate the Papanicolaou smear (Pap smear) results of female patients with psoriasis which were performed for cervical cancer screening before the initiation of biological agent treatment. Between April 2019 and November 2021, Pap smear results of female patients with psoriasis were reviewed retrospectively. This study included 70 female psoriasis patients with a mean age of 48.41±11.62 years. 49 (70%) patients were biologically naive, whereas 21 (30%) patients previously received biological agents. Obscuring inflammation was reported in 33 (47.1%) patients. Atrophy, intermediate cell predominance, reactive cellular changes due to inflammation, and both atrophy and reactive cellular changes were detected in 15 (21.4%), 7 (10%), 3 (4.3%) patients, and 1 (1.4%) patient, respectively. No malignancy or intraepithelial lesion was observed in 69 (98.6%) patients, whereas atypical squamous cells of undetermined significance were reported in 1 (1.4%) patient. Infections such as bacterial vaginosis, candidiasis, and actinomycosis were detected in 13 (18.6%) patients. Pap smear tests should be performed in female psoriasis patients to detect premalignant lesions of the cervix before the initiation of biological agent treatment. Moreover, psoriasis treatment guidelines should be updated accordingly.*

Keywords: *biological agents; cancer; cervical; psoriasis*

INTRODUCTION

Psoriasis is a chronic inflammatory skin disorder that has been associated with systemic comorbidities such as psoriatic arthritis, cardiovascular disorders, and metabolic syndrome [1,2]. Furthermore, increased risk of developing cancer and cancer mortality have been reported in patients with psoriasis [3-6]. Lymphoma, lung, bladder, colorectal, liver, and kidney cancers have been related to psoriasis [4,7]. It has been suggested that predisposition to obesity, lifestyle factors such as smoking, chronic inflammation, and immunosuppressive drugs used for the treatment of psoriasis might play a role in the etiopathogenesis of cancer in patients with psoriasis [4,8]. Cancer risk increases with disease severity [9]. Patients with severe psoriasis are usually treated with systemic immunosuppressive drugs for a long period of time to control disease [8].

Biological agents such as tumor necrosis factor-α (TNF-α) inhibitors and interleukin (IL) 12/23, IL-23, and IL-17 inhibitors are choices of treatment in psoriasis [10]. TNF-α is an inflammatory cytokine that plays a role in the regulation of cell proliferation and apoptosis [11]. IL-12 and IL-23 show anti-tumor effects, whereas IL-17 has both anti-tumor and tumorigenic effects [10]. Therefore, concerns have been raised that treatment with biological agents might lead to increased cancer risk in psoriasis patients [10,12]. Joint American Academy of Dermatology-National Psoriasis Foundation guidelines recommends performing age-appropriate cancer screening tests in psoriasis patients treated with biological agents [13].

Cervical cancer is the third most common cancer in women globally. Moreover, cervical cancer is the second leading cause of cancer-related mortality in women. Papanicolaou (Pap) smear is the main test used to screen for cervical cancer. Colposcopy and biopsy may be performed in patients with atypical epithelial cells on Pap smear results [14].

Within this study, we evaluated Pap smear results of female patients with psoriasis which were performed to detect premalignant lesions of the cervix and cervical cancer before the initiation of biological agent treatment.

MATERIALS AND METHODS

Gazi University Ethics Committee approval was obtained prior to this study (approval number: 2021-1067). Between April 2019 and November 2021, Pap smear results of female patients with psoriasis which were performed for cervical cancer screening before the initiation of biological agent treatment were reviewed retrospectively.

Specimen types such as liquid-based and conventional Pap smear, presence of endocervical transformation zone component, quality indicators such as obscuring inflammation and blood, non-neoplastic findings such as atrophy and reactive cellular changes, general categorization, and detected microorganisms were evaluated. Patients with inadequate Pap smear specimens for evaluation were excluded from the study.

Statistical analysis was performed using SPSS version 20.0. Continuous variables were defined as the mean (±) standard deviation and categorical variables were expressed as percentages. Differences between the two groups were detected with a chi-square test. P<0.05 was considered statistically significant.

RESULTS

This study included 70 female patients with psoriasis with a mean age of 48.41±11.62 years (range: 25-74 years). 54 (77.1%) patients had psoriasis vulgaris, 8 (11.4%) patients had generalized pustular psoriasis, 5 (7.1%) patients had palmoplantar psoriasis, 2 (2.9%) patients had palmoplantar pustular psoriasis and 1 (1.4%) patient had inverse psoriasis. The mean disease duration was 15.71±11.51 years (range: 1-50 years). 26 (37.1%) patients had psoriatic arthritis. Past medical history was unremarkable in 37 (52.9%) patients. Moreover, 24 (34.3%) patients had hypertension, 16 (22.9%) patients had diabetes, 5 (7.1%) patients had chronic hepatitis B virus infection, 4 (5.7%) patients had hypothyroidism, 4 (5.7%) patients had coronary artery disease, 3 (4.3%) patients had hyperlipidemia, 2 (2.9) patients had chronic obstructive pulmonary disease, 2 (2.9) patients had asthma and 1 (1.4%) patient had steatohepatitis. 69 (98.6%) patients were treated with conventional systemic treatments such as methotrexate, cyclosporine, and acitretin, and 18 (25.7%) patients were previously treated with phototherapy. 49 (70%) patients were biologic naive, however, 21 (30%) patients were previously treated with biological agents. Among them, 6 (8.6%) patients received infliximab, 5 (7.1%) patients received adalimumab, 3 (4.3%) patients received etanercept, 2 (2.9%) patients received ustekinumab, 1 (1.4%) patient received ixekizumab, 1 (1.4%) patient received secukinumab and 1 (1.4%) patient received certolizumab pegol. In addition, 1 (1.4%) patient was treated with both adalimumab and etanercept, and 1 (1.4%) patient was previously treated with both infliximab and etanercept.

Specimen type was liquid-based in 46 (65.7%) patients and conventional Pap smear in 24 (34.3%) patients (Table 1). The presence of endocervical transformation zone components was reported in 47 (67.1%) patients.

Table 1: Pap smear results of the patients with psoriasis before biological agent treatment

	n (%)			
Specimen type	Liquid-based 46 (65.7%)	Conventional 24 (34.3%)		
Endocervical transformation zone	Present 47 (67.1%)	Absent 23 (32.9%)		
The other quality indicators	Obscuring inflammation 33 (47.1%)	Obscuring blood 1 (1.4%)		
Non-neoplastic findings	Atrophy 15 (21.4%)	Intermediate cell predominance 7 (10%)	Reactive cellular changes due to inflammation 3 (4.3%)	Atrophy+reactive cellular changes 1 (1.4%)
General categorization	Negative for malignancy 69 (98.6%)	Atypical squamous cells 1 (1.4%)		
Microorganisms	None 57 (81.4%)	Bacterial vaginosis 6 (8.6%)	Candida 6 (8.6%)	Bacterial vaginosis+ Actinomyces 1 (1.4%)
3-dimensional cell groups	1 (1.4%)			

Atypical squamous cells of undetermined significance were reported in 1 (1.4%) patient. Fungal organisms consistent with Candida were encountered in 6 (8.6%) patients, 3 (4.3%) of them had fungal organisms morphologically consistent with Candida glabrata. In addition, three dimensional groups of endocervical cell shedding which might be associated with benign cervical lesions such as polyp or papillary cervicitis was reported in 1 (1.4%) patient.

However, the endocervical transformation zone component was absent and thus squamous epithelial cells were evaluated in 23 (32.9%) patients. Among other quality indicators, obscuring with inflammation was reported in 33 (47.1%) patients, and obscuring with blood was reported in 1 (1.4%) patient. As a non-neoplastic finding, atrophy was detected in 15 (21.4%) patients, intermediate cell predominance was detected in 7 (10%) patients, and reactive cellular changes due to inflammation were detected in 3 (4.3%) patients. In addition, 1 (1.4%) patient showed both atrophy and reactive cellular changes. No malignancy or intraepithelial lesion was observed in 69 (98.6%) patients, however, epithelial cell abnormality was detected in 1 (1.4%) patient. Atypical squamous cells of undetermined significance (ASC-US) [15] were reported in the latter. The patient with ASC-US was a 44-year-old female with a 36-year history of psoriasis vulgaris and psoriatic arthritis who had been previously treated with methotrexate and infliximab. No microorganism was detected in the Pap smear results of 57 (81.4%) patients. However, 6 (8.6%) patients showed flora change suggesting bacterial vaginosis. Fungal organisms consistent with Candida were encountered in 3 (4.3%) patients and fungal organisms morphologically consistent with Candida glabrata were encountered in 3 (4.3%) patients. Pap smear result of 1 (1.4%) patient revealed both flora changes suggesting bacterial vaginosis and microorganisms consistent with Actinomyces. Three-dimensional groups of endocervical cell shedding which might be associated with benign cervical lesions such as polyp or papillary cervicitis were reported in 1 (1.4%) patient.

Patients with atrophy on Pap smear were statistically significantly older than those who did not have atrophy on Pap smear (the mean age: 60.44±6.25 and 44.85±10.41 years, respectively) (p<0.001). On the other hand, the mean age of the patients with inflammation on Pap smear (44.88±8.98 years) was statistically significantly lower than the mean age of the patients without inflammation on Pap smear (51.57±12.87 years) (p=0.015). Inflammation on Pap smear was observed in 26 (37.1%) patients with psoriasis vulgaris, 3 (4.3%) patients with palmoplantar psoriasis, 2 (2.9%) patients with generalized pustular psoriasis, 1 (1.4%) patient with palmoplantar pustular psoriasis and 1 (1.4%) patient with inverse psoriasis. No statistically significant difference was detected between psoriasis type and inflammation on Pap smear (p=0.549). The mean disease duration with and without inflammation on Pap smear was 13.67±10.33 and 17.54±12.31 years, respectively (p=0.161). 13 (18.6%) patients with inflammation on Pap smear had psoriatic arthritis, and 20 (28.6%) patients with inflammation on Pap smear did not have psoriatic arthritis. No statistically significant difference was detected between psoriatic arthritis and inflammation on Pap smear (p=0.713). 11 (15.7%) patients with inflammation on Pap smear had accompanying comorbidities whereas 22 (31.4%) of the patients with inflammation had an unremarkable past medical history (p=0.029). 25 (35.7%) patients with inflammation on Pap smear were biologic naive, whereas 8 (11.4%) patients with inflammation on Pap smear received former biological agent treatment (p=0.321). Among 33 patients with inflammation, only 8 of them had Pap smear results suggesting infection such as bacterial vaginosis or candidiasis (p=0.249).

DISCUSSION

Cervical cancer screening aims for the early detection of premalignant and malignant lesions in order to reduce cervical cancer-related mortality [16]. US Preventive Services Task Force (USPSTF) recommends performing cervical cytology every 3 years in females between the ages of 21 and 29. Between the ages of 30 and 65, it is recommended to perform cervical cytology every 3 years, high-risk human papillomavirus (HPV) testing every 5 years, or both tests every 5 years. Cervical cancer screening is not recommended before 21 years of age and in females older than 65 without high-risk factors for cervical cancer.

According to USPSTF, immunocompromised individuals, patients with human immunodeficiency virus (HIV) infection, and individuals who were exposed in utero to diethylstilbestrol and previously treated for a high-grade precancerous lesion or cervical cancer are at high risk for cervical cancer. Individualized programs for cervical cancer screening have been recommended in the follow-up of these patients [17]. The American Cancer Society (ACS) recommends initiating cervical cancer screening at the age of 25. Between ages 25 and 65, primary HPV tests such as Onclarity HPV are preferred every 5 years. When primary HPV testing is unavailable, both Pap smear and HPV tests such as Digene hybrid capture 2 are recommended every 5 years, or Pap smear alone may be performed every 3 years. Cervical cancer screening should be ceased in women older than 65 with normal screening results for the last 10 years. However, these individuals should not have been diagnosed with cervical intraepithelial neoplasia 2 or more advanced disease for the last 25 years [18]. World Health Organization (WHO) recommends starting cervical cancer screening at the age of 30 in the general population and in women aged 25 with HIV infection. Primarily, HPV DNA detection is recommended every 5 to 10 years in the general population and every 3 to 5 years in women with HIV infection. If HPV-DNA testing is unavailable, either visual inspection with acetic acid (VIA) or cytology may be performed in both groups.

Screening is discontinued both in the general population and in women with HIV infection after 50 years of age [19]. According to the American College of Obstetricians and

Gynecologists (ACOG), cervical cancer screening should be started at 21 years of age. Cytology is preferred for cervical cancer screening in women aged 21-29 years. However, women aged 25-29 with an average risk for cervical cancer can also be screened by high-risk HPV testing every 5 years [20].

The age to start cervical cancer screening, primarily preferred screening tests, screening intervals, and age to stop screening differ in WHO and cervical cancer screening guidelines [17-19]. Moreover, recommendations about immunocompromised individuals such as patients with HIV infection and solid organ transplantation have not been detailed by USPSTF, whereas, in these patients, ACS recommends cytology annually between ages 21-29 and cytology as well as high-risk HPV testing every 3 years between ages 30-65 [21]. Therefore, we suggest that guidelines for the treatment of psoriasis with biological agents should include detailed information on cervical cancer screening in order to guide both physicians and female patients with psoriasis [19].

Studies investigating the risk of cervical cancer in women with psoriasis are inadequate and conflicting results have been reported on the risk of cervical cancer in patients with systemic inflammatory diseases [22,23]. For instance, Moscicki et al. reviewed the risk of cervical cancer in patients with immunosuppression for reasons other than HIV infection and in patients with autoimmune diseases. Moscicki et al. suggested that the risk for the development of cervical cancer increased in patients with inflammatory bowel disease and rheumatoid arthritis who were under immuno-suppressive treatment and in patients with systemic lupus erythematosus regardless of treatment [22]. On the other hand, Kim et al. reported that the risk of cervical dysplasia and cervical cancer were higher in patients with systemic inflammatory diseases such as rheumatoid arthritis and systemic lupus erythematosus but not different in patients with psoriasis and inflammatory bowel disease compared to women without systemic inflammatory diseases. Kim et al. suggested that the results might be affected by the variety in systemic inflammation levels between patient groups and low rates of administration of immunosuppressive medication in patients with psoriasis and inflammatory bowel disease [23].

Patients with psoriasis who are treated with biological agents may not undergo necessary cancer screening tests [24]. Kim et al. revealed that only 55% of the patients with psoriasis were admitted to a gynecologist at least once within an approximately two-year follow-up [23]. Silveira et al. suggested that 25.2% of the patients with psoriasis who were under biological agent treatment did not have necessary laboratory tests during the previous year [25]. Barbieri et al. reported that the rate of attendance of cervical cancer screening in psoriasis patients treated with biological agents was similar in patients with hypertension, however, 9% higher than in the general population [24].

CONCLUSION

Within this study, Pap smear results of 70 women with psoriasis were evaluated before the initiation of biological agent treatment. Atypical squamous cells were detected in 1 (1.4%) patient, whereas Pap smear results revealed infections such as bacterial vaginosis, candidiasis, and actinomycosis in 13 (18.6%) patients. Furthermore, obscuring with inflammation was reported in 33 (47.1%) patients. Inflammation on Pap smear was more commonly detected in younger patients, however, no statistically significant association was observed between inflammation on Pap smear and psoriasis type, disease duration, the existence of psoriatic arthritis, and previous biological agent treatment (p=0.549, p=0.161, p=0.713, p=0.321, respectively). Hence, we suggest that a Pap smear test should be performed in female psoriasis patients to detect premalignant lesions of the cervix before the initiation of biological agent treatment. Moreover, psoriasis treatment guidelines should be updated accordingly.

Abstract: *Background and Objectives: Chronic Kidney Disease (CKD) affects 6,7% of the adult population in Romania and is associated with high morbidity. About one out of three adults with diabetes has kidney disease. According to current literature data, the prevalence of diabetes is very high, up to 11,6%, of whom 2,4% had undiagnosed diabetes, and is the leading cause of kidney damage and the need for renal replacement therapy (RRT). COVID-19 has brought with it a lot of unanswered questions, regarding the risk factors, the disease evolution, and the treatment possibilities. It became clear that diabetic kidney disease (DKD) is among the independent risk factors that predict unfavorable outcomes upon SARS-CoV-2 infection, so we aimed to evaluate the characteristics of diabetic and non-diabetic dialyzed patients, COVID-19 positive. Materials and Methods: It is an observational, single-center study that analyzed type 2 diabetes mellitus and non–diabetic patients in maintenance hemodialysis hospitalized for SARS CoV-2 infection. Results: A total of 101 adult dialyzed patients were admitted with a SARS-CoV-2 RT-PCR positive test, out of which 42 had a long history of diabetes mellitus type 2 and 59 of them have been known with other etiologies of CKD. Hypertension and heart disease were the most commonly associated comorbidities. Inflammatory markers and anemia were significantly increased in diabetic patients compared to non-diabetic. Conclusions: We found that anemia was more severe in patients COVID-19-positive MHD T2DM patients.*

Keywords: *COVID-19; diabetic nephropathy; diabetic kidney disease; mortality*

INTRODUCTION

The introduction of the term chronic kidney disease (CKD) was followed by the discovery of an unexpectedly high prevalence of CKD. According to PREDATORR study, the prevalence of CKD in Romania was estimated at 6.7% [1]. The real problem with this finding is the high morbidity and mortality burden associated with advanced stages of CKD. During COVID-19 pandemics, the mortality rates associated with SARS-CoV-2 infection were higher in maintenance hemodialysis patients (MHD) than in the non-renal population, varying between 27-41% [2], reaching 50% in other studies. [3]. The maintenance hemodialysis patients are even at a greater risk for death, as was observed in recent studies [4].

Another risk factor for unfavorable outcomes in COVID-19 infection is type 2 diabetes mellitus (T2DM) [5]. According to the International Diabetes Federation, there are 1.2 million patients with diabetes mellitus in Romania [6].

The association between diabetes and chronic kidney disease is extremely common, being the main cause of end-stage kidney disease (ESKD), in more than 40% of patients worldwide [7], even more than the traditional nephrological pathology, such as glomerular diseases. Poor glycemic control has been proven to be a risk factor for progression to ESKD, renal replacement therapy (RRT), and fatal cardiovascular events. During the COVID-19 pandemic, studies have reported diabetes mellitus (DM) to be associated with a two-fold increase in mortality as well as increased severity of COVID-19 disease, as compared to non-DM patients [8]. Maintaining optimal glycemic control is crucial for avoiding severe complications, and continuous glucose monitoring devices could improve glycemic control for patients with type 2 diabetes, thus decreasing the rates of high morbidity as seen in recent studies [9]. Given the fact that diabetes is a major concern worldwide, new biomarkers for glycemic control need to be found for better diagnosis and treatment [10]

The aim of the present study was to evaluate the characteristics of COVID-19 patients with DM as compared to non-DM COVID-19 population.

MATERIALS AND METHODS

It is an observational, single-center study conducted in the Nephrology Clinic of Saint John Emergency Clinical Hospital Bucharest and includes data on MHD patients admitted between November 2021-March 2022. COVID-19 disease was confirmed by positive real-time polymerase chain reaction (RT-PCR). The data was collected from the hospital's electronic medical database. The study was conducted according to the Declaration of Helsinki on human rights.

The protocol of the study was approved by the Institutional Ethics Committee. Considering the observational character of the study, the informed consent was waived by the Ethics Committee.

We collected data regarding age, gender, disease severity, oxygen supplementation need, etiology of chronic kidney disease (CKD), laboratory tests (hemoglobin levels, leukocyte, lymphocyte and platelet counts, serum albumin, C-reactive protein (CRP), procalcitonin, interleukin-6 (IL-6) and data about infectious and non-infectious complications. We divided the study population into two groups based on the T2DM status (T2DM vs. non-DM) and compared continuous variables from the two groups using the nonparametric Mann-Whitney U test and parametric t-test. We considered statistically significant a p-value of less than 0.05. The software used was Graph Pad Prism 6.0.

The limits of this study are represented by its retrospective character, including the small number of patients.

RESULTS

A complete physical examination was required for assessing the clinical status of patients and the performance status was evaluated according to the ECOG scale. Most patients (61.7%) presented with good performance status (ECOG 0), 35.6% with ECOG 1, and 0.7% with ECOG 2.

The study group consisted of 101 consecutive adults (>18 years of age) MHD patients who were admitted with a SARS-CoV-2 RT-PCR positive test, out of which 42 (48.5%) had a diagnosis of diabetic kidney disease (DKD), and 59 (51.5%) have been known with other etiologies of CKD, predominantly represented by hypertensive nephropathy (33.89%), chronic obstructive tubulointerstitial nephropathy (11.86%), and autosomal dominant polycystic kidney disease (8.47%).

For the study population, demographic and clinical characteristics are presented in Table 1.

In the T2DM group, the median age was 65.69±31.87 years (CI 95%) and the majority of the patients were men (66.6%). More than 50% of patients were obese and the most common comorbidities were represented by hypertension (100%), chronic coronary heart disease (61.9%), atherosclerosis (61.9%), followed by pulmonary disease (11.9%), and active malignancies (7.1%). In the T2DM study population, 42.8% of patients required noninvasive oxygen therapy at admission, out of which 11.1% needed positive pressure ventilation in evolution, while 11.9% needed positive pressure ventilation from admission and 23.8% required mechanical ventilation. In the T2DM group, hemorrhagic complications were observed in 16.6% of patients. We identified thrombosis in 4.76% of patients (arteriovenous fistula thrombosis, lower limb deep vein thrombosis, and splenic infarction). Sepsis was identified in 30.9% of the cases and one patient developed Clostridioides difficile colitis. The recorded mortality rate for the T2-DM patients was 42.5%, out of which 72.2% of the deaths were due to sepsis (Figure 1).

In the non-diabetes study group, the median age was 64.33 ±3.08 years (CI 95%), the majority being men (64.4%). The obesity rates were lower (30.5%) than those in the T2DM group and 89.8% were hypertensive. Chronic coronary heart disease (47.4%) and atherosclerosis (40.6%) were observed at lower rates, with higher rates of chronic pulmonary diseases (18.6%) and active malignancies (20.3%).

Regarding respiratory insufficiency management, we observed that when compared with T2DM patients, 49.1% of non-DM required non-invasive oxygen therapy at admission, with a statistically significant difference, but the rates for assisted ventilation (positive pressure ventilation (PPV) and mechanical ventilation (MV) were lower, 10.1% and 18.6%, respectively.

Table 1: Demographic and clinical characteristics and the significant differences

	Overall	T2DMgroup	Non-DM group	P value
Patient number (N)	101	42	59	
Demographic data				
Age (mean, years)	64.901 ±2.241	65.69 ±31.87	64.339 ±3.08	0.4111
Gender (%)				
Female (N, %)	35	14 (33%)	21 (35.6%)	0.6573
Male (N, %)	66	28 (67%)	38 (64.4%)	0.2390
Risk factors				
Obesity (N, %)	45	27 (64.2%)	18 (30.5%)	0.5796
Atherosclerosis (N, %)	50	26 (61.9%)	24 (40.6%)	0.3712
Comorbidities				
Hypertension (N, %)	95	42 (100%)	53 (89.8%)	0.8127
Ischemic heart disease (N, %)	54	26 (61.9%)	28 (47.4%)	0.2450
History of neoplasm (N, %)	15	3 (7.14%)	12 (20.3%)	0.7672
Pulmonary disease (N, %)	16	5 (11.9%)	11 (18.6%)	0.7732
Supplemental oxygen				
Nasal cannula (N, %)	47	18 (42.8%)	29 (49.1%)	0.0440
PPV (N, %)	13	7 (16.6%)	6 (10.1%)	0.7854
MV (N, %)	21	10 (23.8%)	11 (18.6%)	0.7310
Complications				
Hemorrhagic (N, %)	24	7 (16.6%)	17 (28.8%)	0.6509
Thrombosis (N, %)	4	2 (4.7%)	2 (3.3%)	0.8230
Infection (N, %)	23	13 (30.9%)	10 (25.4%)	0.7258
Laboratory testing				
Hemoglobin <12 g/dL (N,%)	85	34 (80.9%)	51 (86.4%)	0.0173
WBC > 11 x $10^3/mm^3$ (N, %)	21	11 (26.9%)	10 (16.9%)	0.0001
CRP > 5 ng/mL (N, %)	98	40 (95.2%)	58 (98.3%)	0.0001
Procalcitonin >0,05 ng/mL (N, %)	101	42 (100%)	59 (100%)	0.0001
Interleukin-6 > 7 pg/mL (N, %)	98	41 (97.6%)	57 (93.2%)	0.0001
Mortality (N, %)	39	19 (45.2%)	20 (33.8%)	0.5685

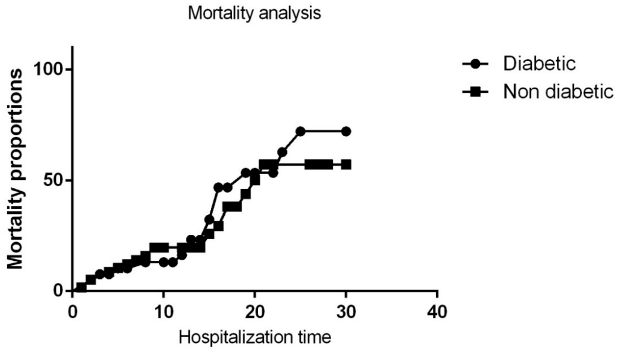

Figure 1: Mortality analysis between diabetic and non-diabetic patients

Hemorrhagic complications were observed in 28.8% of patients in the non-DM group, more frequently with soft tissue hematoma and only two cases of thrombosis. Infectious complications were observed in 25.4% of the non-DM patients (66.6% represented by sepsis and 33.3% by Clostridioides difficile colitis). The mortality rates for the non-DM group were lower (32.2%) when compared to the T2DM group.

We analyzed biological parameters in both groups. In the

T2DM group, 80.9% of patients had anemia (Hgb<12 g/dL), with a higher proportion in the non-DM group, accounting for 86.4%. Inflammatory status was assessed by leukocyte count, lymphocyte count, C-Reactive Protein level, procalcitonin, and Interleukin-6 (IL-6) levels. Leukocytosis (>11.000/mm^3) was present at admission in 26.9% of cases, while lymphopenia in 61.9% of cases.

C- Reactive Protein, procalcitonin, and IL-6 levels were increased at admission in almost all T2DM patients namely 95.2%, 100%, and 97.6% respectively. The non-DM-group also accounted for high inflammatory parameters, leukocytosis in 16.9%, C-Reactive Protein >5 mg/L in 98.3%, procalcitonin >0,05 ng/mL in 100%, and IL-6 >7 pg/mL in 93.2%. We found statistically significant differences when comparing the two groups ($p<0.001$). Hypoalbuminemia (serum albumin level <3.4 mg/dL) was noted in higher rates in the non-DM group (27.1%) as compared with T2DM patients (23.8%), with statistically significant differences (Table 1).

DISCUSSION

Diabetes is a major cause of chronic kidney disease, accounting for more than 50% of MHD patients all around the world, exceeding traditional kidney diseases [11,12]. Early COVID-19 reports mentioned DM among the most important risk factors for severe disease and increased mortality due to SARS-CoV-2 infection. The majority of COVID-19 reports stated that CKD is independently a risk factor for poor outcomes, with adjusted mortality in CKD and HD patients being described to be 2 to 3 times higher [4].

All of the 42 T2DM patients were known with hypertension. It is well known the equipotent relationship between CKD and hypertension: hypertension can cause CKD and CKD is a risk factor for hypertension. Also, DM and hypertension frequently occur together, with a substantial overlap between DM and hypertension in disease mechanisms. In the non-DM group, 89.8% were hypertensive, with lower rates when compared with the T2DM group, approaching the literature data that DM and CKD cause high blood pressure with poor control [13], and with a high mortality risk in SARS-CoV-2 infection [14,15].

Obesity rates were higher in the T2DM group, more than 50% vs 30.5%. In the first meta-analysis of obese patients and COVID-19, was stated that higher body mass index was associated with intensive care unit admission and critical disease [16], by decreasing expiratory reserve volume, diaphragm excursion, and restricting ventilation.

In DM patients, the risk of fatal cardiovascular events is much higher compared to the general population. A close link exists between diabetes and cardiovascular disease which is the most prevalent cause of morbidity and mortality in diabetic patients [17]. In the presented study, coronary heart disease was more frequently observed in T2DM patients as compared to non-DM patients. Also, atherosclerosis was seen with higher prevalence in the DM group, approaching the literature and the current evidence that diabetes dramatically accelerates atherosclerosis [18], all of this constellation increasing the COVID-19 mortality [19].

Some malignancies are shown to increase the risk of kidney failure [20,21,22] In our study, patients with active malignancies were in a higher proportion in the non-DM group.

Anemia is more commonly associated with diabetic kidney disease [23]. When comparing the two study groups, we found that anemia is a risk factor for poor outcomes in MHD T2DM patients.

In general, infectious diseases are more frequent and severe in patients with DM, due to the chronic hyperglycemic status that promotes immune dysfunction [24]. Studied T2DM patients presented with significantly altered inflammation markers compared to the non-DM group. Hypoalbuminemia has been observed in the T2DM group, to a lesser extent compared to non-DM, but the differences were statistically significant. T2DM status and impaired immune system are risk factors for poor outcomes in SARS-CoV-2 infected patients. The mortality rates were higher in the T2DM group, although the differences were not statistically significant.

CONCLUSION

In conclusion, we found that anemia is more severe in COVID-19 MHD T2DM patients. The severity of anemia in the T2DM group was consistent with significantly altered inflammatory markers. New biomarkers and studies are needed for better anemia management and more specific biomarkers that correlate the inflammatory status with the infectious disease.

We aim for a future in which we have as many studies as possible that include hemodialysis patients, a special category of patients due to the high morbidity and mortality associated with it, and also due to the important social impact.

The patient`s data used to support the findings of this study is available from the corresponding author upon request.

Abstract: *Background: As total hip replacement cases increase year after year, registry-wide data becomes increasingly important in order to assess pathology distribution, reimbursement efficiency as well as physician performance. In order to assess all these factors patient evolution needs to be documented after surgery as well, but the main impediment to doing this is losing patients to follow-up. For this reason, the present study aims to perform a descriptive analysis of the hospital's internal registry data as well as to determine what percentage of patients can be expected to return to follow-up after total hip replacement. Methods: A query of the hospital's internal registry data in the last years was performed. Patient demographics, county distribution as well as ICD-10 code usage were documented. Data standardization was performed to determine the probability and cumulative distribution of the patient's age. The chi2 test of independence was used to assess whether there is a correlation between the patient's gender and ICD-10 codes. Pot hoc power analysis was performed to assess the accuracy of correlation analysis. Results: Only 29.6% of the patients undergoing total hip replacement are from the county within which the hospital is located. 25% of the patients were under 60 years old. Conclusions: Current registry data reveals that most patients undergoing total hip replacement are around 67.5 ± 11 years old, suffer from unilateral or bilateral primary or secondary hip osteoarthritis and only 29.6% of them are likely to return to follow-up.*

Keywords: *total hip replacement; ICD-10; registry; statistical analysis*

INTRODUCTION

Over 1 million total hip arthroplasty (THA) surgeries have been performed globally in the last year and this number is rising for both primary and revision procedures [1]. In the United States, the rate of primary total hip arthroplasties increased by 50%, from 47 per 100 000 people to 69 per 100 000 people, with a market size of nearly 2.30 billion USD [2]. With over 305 operations per 100,000 residents, Switzerland continues to lead the list of countries in Europe with the highest hip replacement rate, according to a 2016 report from the World Organization for Cooperation and Regional Development (OECD) [3].

In Romania, the annual rate of primary hip replacement has climbed dramatically during the previous 15 years, 51.8 out of every 100,000 people underwent a main hip replacement procedure in 2015, whereas 2.7 out of every 100,000 people required a hip revision surgery [4,5].

The demand for hip implants is expected to increase as a result of adequate health insurance coverage and reimbursement laws for joint replacement surgeries [6].

In our country, THAs were performed mostly on patients between 60 and 69 years old. Male patients are more prevalent in the 50-59 age range and younger age groups, while female patients are more likely to have THAs after the age of 59. With a total of 29,497 female patients and 19,675 male patients, women over the age of 59 make up the clear majority [5].

Although THA has demonstrated outstanding short and long-term results, the revision rate has remained constant over the past few decades despite improvements in surgical technique and implant design [7,8].

In the US the most common causes for re-intervention were: instability (22%), mechanical loosening (20%), infection (15%), implant failure (10%), osteolysis (7%), and periprosthetic fracture (6%) [9,10]. In Romania, the most common reasons for revision surgery are acetabular defects (mostly acetabular loosening and osteolysis), femoral defects, and other (un-standardized reasons for revision in 20%-25% of the cases), followed by were, luxation, infection, periprosthetic fracture and broken implants [11].

It has been established that primary surgeries use fewer financial resources than revision surgeries [12]. In order to maintain the sustainability of their finances, institutions must comprehend the costs and durability of these interventions [13]. Implants cost to make up a significant portion of the entire hospitalization bill (for revision surgery especially) and are a key area for cost-cutting overall which demands proper financial planning [14].

There is a wide range in reimbursements for both primary and revision surgeries, possibly in part because of the diagnosis-related group (DRG), intrinsic unpredictability, and complexity of these procedures with a rising need to reconcile the clinical challenges with the available technical stock [6,13]. That is why we consider that analyzing and supporting the cost-effectiveness of surveillance measures is a necessity. Orthopedic specialists generally concur that some follow-up after THA is important [11]. Nowadays there are no clear standardized instructions regarding the timing of the subsequent visits following hip replacement interventions [15]. The identification of asymptomatic patients who need revision surgery remains one of the primary justifications for early and late routine follow-ups [16].

There are only five recommended protocols for THA follow-up visits that are well described, according to a systematic review of the literature and the content of orthopedic associations' websites, with a lot of variation in the suggested follow-up frequency and duration [17]. The latter is simply mentioning the necessity of routine follow-up visits without defining their timing, duration, or their cost-effectiveness [18,19].

According to earlier research, patients who don't follow up with their surgeon regularly are more likely to experience worse outcomes and require additional surgical intervention at a different location [18,20]. Regardless of its importance, postoperative evaluation places a heavy load and financial burden on patients, families, and tertiary healthcare systems which have to manage a rising number of new patients [21,22].

This study's goal was to assess patient compliance with clinical follow-up in a line of patients who underwent hip surgery in different surgical centers in our country. In addition, we aim to analyze the positive and negative predictors for clinical follow-up compliance.

MATERIALS AND METHODS

Prior to the study's inception, ethical approval was sought and received. The aim of the study was to investigate the hospital's internal hip arthroplasty registry between 2018 and 2022 in order to determine patient gender and age distribution as well as how many patients would be likely to return to follow-up after surgery. An arbitrary distance boundary was set to only include the county in which the hospital is situated (B, Bucharest County). A descriptive analysis of ICD-10 codes frequency and gender distribution was also generated. Patients undergoing cemented and uncemented total hip arthroplasty were eligible for inclusion.

In order to plot an age frequency distribution, z-scores were generated and from them, the frequency distribution was plotted in Microsoft Excel.

A chi2 test of independence was performed to assess whether there is a gender propensity for any ICD-10 scores. Posthoc power analysis was also conducted to judge the appropriateness of the chi2 test results.

Further stratification based on relevant age groups has been performed in order to identify diagnostic patterns. Relevant age groups were constructed as follows: "Under 30", "30-39", "40-49", "50-59", and "60 and above". A histogram was used to present diagnostic patterns in each age group.

Data gathering, analysis, and storage were performed using SPSS v.26, Microsoft Excel, and Python programming language v.2.7.

RESULTS

After ethical approval, 929 patients were detected within the specified period. Patient age and gender distribution are presented in Table 1. Figure 1 presents the patient's distribution as a function of the county with 29.6% of the patients undergoing cemented or uncemented hip arthroplasty coming from the county in which the hospital is located, Bucharest. Figure 2 and Table 1 show that most often, patients 67.5 years or older undergo total hip arthroplasty. At the same time, a significant proportion of the included patients are under the age of 60, 25%. ICD-10 codes M16.1 "Unilateral primary osteoarthritis of the hip" and M16.7 "Other unilateral secondary osteoarthritis of the hip" were the most used, accounting for almost 45% of cases. ICD-10 codes M16.6 "Other bilateral secondary osteoarthritis of the hip" and M16.0 "Bilateral primary osteoarthritis of the hip" were the second most used codes accounting for 22.4% of cases.

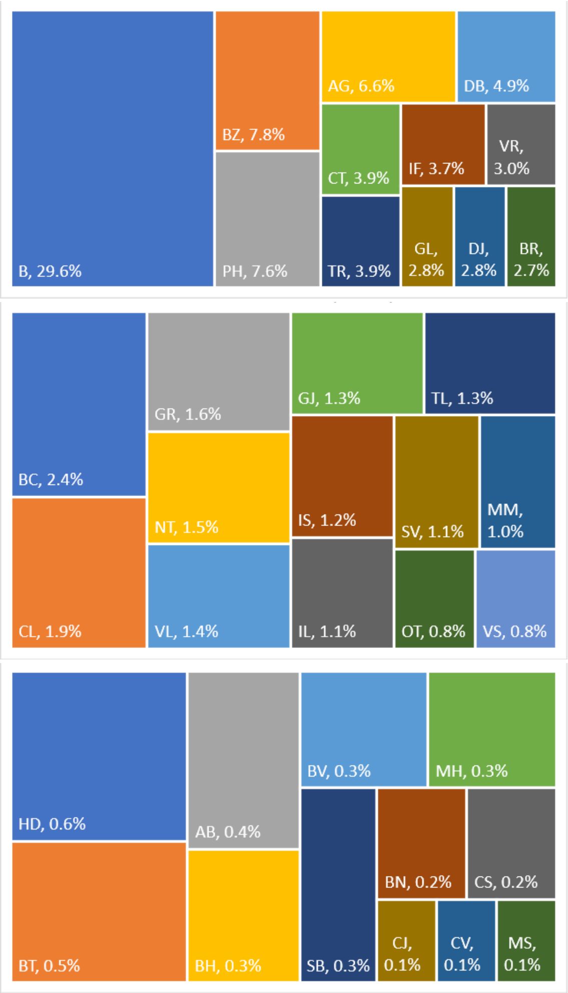

Figure 1: Visual representation of patient distribution by county. The figure is divided into three components for ease of interpretation. Each county name was abbreviated according to its national code

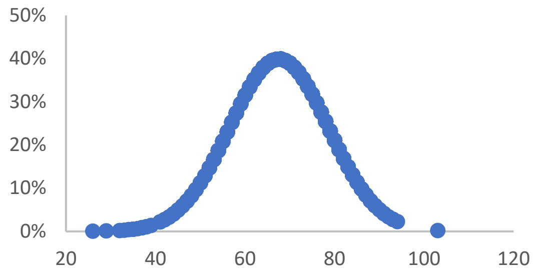

Figure 2: Patient age-standardized probability distribution

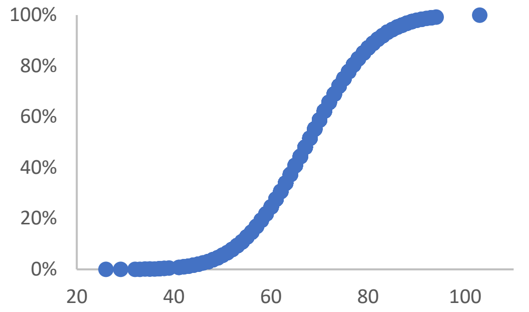

Figure 3: Patient age-standardized cumulative distribution

Figure 5 presents a descriptive analysis of each used ICD-10 code as a function of gender distribution. The chi2 test of independence has not identified any significant correlations between gender and any ICD-10 code. However, post hoc power analysis has shown that the sample size in each subgroup was insufficient to detect a meaningful effect. For this reason, we cannot draw any meaningful conclusions from the subgroup analysis. Age group diagnostic patterns reveal that the most often encountered patients are the ones at 60 years or above followed by the ones within the 50 to 59 age group. Diagnostic patterns do not reveal any significant differences between groups, M16.1 being the most often encountered diagnostic code as depicted in Figure 6.

DISCUSSION

The results presented indicate that patient follow-up poses significant challenges, as only 29.6% of the patients included were deemed suitable for returning to the surgical center for follow-up. In addition, it is anticipated that these patients will experience the typical follow-up loss rate of 10-20%, regardless of their proximity to the surgical center. The significance of this report lies in its importance for upcoming prospective studies at our hospital, which will enable the precise evaluation of implant durability and patient-reported outcome measures. It is crucial to monitor adverse events during follow-up, as changes in patient-reported outcomes may indicate the likelihood of such events occurring [23].

Tertiary hospitals often face a common issue where patients from various regions across the country are referred to them, making it challenging to monitor their symptoms and track their progress over an extended period. In light of this, remote reporting could serve as a viable solution for these hospitals to maintain contact with their patients and minimize follow-up loss rates, resulting in higher patient reporting rates during prospective studies [24,25].

The age probability and cumulative distributions provided in the report are extremely beneficial for the orthopedics department and healthcare providers, as they enable them to determine when patients are likely to require hip replacement surgery. Simultaneously, these distributions enable all concerned parties to anticipate future budget allocations based on patient age, as older patients are more susceptible to degenerative hip conditions, whereas younger patients are more prone to developmental hip diseases such as dysplasia. As a result, budget allocation can be optimized through informed decision-making, allowing for the advance procurement of specific resources to serve patients promptly after their initial consultation [26,27].

By implementing ICD-10 code reporting and rigorous oversight over its reporting, additional budget optimization can be achieved by providing decision-makers with information on which implants are likely to be required at each hospital [28,29]. Present results highlight the fact that in 45% of cases patients either suffer from “Unilateral primary osteoarthritis of the hip” or “Other unilateral secondary osteoarthritis of the hip”. Patients suffering from primary unilateral osteoarthritis who are 67 years or older most likely require standard uncemented total hip replacements for this reason at least 23.4% (Figure 4) of cases will require standard total hip implants. At the same time, patients suffering from unilateral secondary osteoarthritis most likely developed osteoarthritis secondary to aseptic osteonecrosis of the femoral head [30] while a smaller proportion of younger patients are expected to develop osteoarthritis secondary to acetabular or proximal femoral deformities like acetabular retroversion, excessive femoral anteversion with ace-tabular under coverage, CAM, pincer or mixed femoral-acetabular impingement (FAI) [31–33]. This kind of patient often requires specialized implants in order to accurately reconstruct hip offset and anatomical center of rotation or when associated with the need for femoral derotation or shortening osteotomy [34]. Furthermore, the following 22.4% of cases comprised of “Other bilateral secondary osteoarthritis of the hip”, and “Bilateral primary osteoarthritis of the hip”, signal an important need for sequential or single-step bilateral total hip replacement. Each option has to be considered against its risks. Sequential bilateral hip replacements can be done through any approach and are more suited for patients who do not have a reliable support network and for whom the disease process is not as debilitating [35,36]. Innovative anterior-based hip approaches have made single-step total hip replacement possible, enabling patients to be placed in a supine position while preserving their abductors and external hip rotators. As a result, rehabilitation can be easily carried out, even in patients with bilateral implants [35,36].

Unfortunately, the current employed ICD-10 codes do not allow for a more in-depth analysis of causative relations leading to hip degenerative disease. The prevalent problem is that "secondary" causes of hip osteoarthritis involve intricate clinical conditions that involve spinopelvic interactions, pelvic and femoral orientation, and their interrelationship. Thus, labeling a case as "secondary" hip osteoarthritis alone does not furnish healthcare providers and practitioners with sufficient information to formulate predictable models to attain economic and treatment efficiency [37].

The report emphasizes the significance of registry data while underscoring the current inadequacies in reporting standards that impede advanced clinical and economic planning. These inadequacies underscore the necessity for clinicians and healthcare providers to actively engage with technological advancements, particularly with respect to patient reporting standards and stringent follow-up [24,38–41].

Future research efforts should concentrate on enhancing ICD-10 reporting standards, devising innovative methods for maintaining contact with patients after an intervention, particularly in tertiary hospitals, and furnishing healthcare providers with reliable data that can facilitate efficient planning and procurement, ensuring the utmost standard of healthcare for patients.

CONCLUSION

Registry data provides valuable information to healthcare providers and is a key source of data for healthcare improvements. Healthcare practitioners will most of the time encounter patients 67 ± 11 years old most likely suffering from either unilateral primary or secondary osteoarthritis. Based on the available data surgeons could expect that standard total hip implants will most often than not meet patient needs and be sufficient to reconstruct the native hip anatomy.

Correspondence: sajad.shiri@live.com

Abstract: *A multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes plays a vital role in enhancing preparedness, response, and recovery capabilities in the face of CBRN incidents. A multipurpose hall for CBRN purposes provides a dedicated and specialized environment to support CBRN preparedness, response, and recovery efforts. It enhances coordination, facilitates training and exercises, ensures proper equipment storage, and fosters collaboration, ultimately strengthening the ability to protect personnel, mitigate risks, and minimize the impact of CBRN incidents. This study is qualitative research based on the content analysis method. To design and build multipurpose halls for CBRN events, this study can be used as a checklist. The purpose of this study is to collect important factors and sub-factors in the design, construction, and equipping of buildings and multi-purpose CBRN structures.*

Keywords: *Multipurpose Hall, CBRNe, Disaster, Emergency*

INTRODUCTION

A multi-purpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes plays an important role in handling CBRN incidents and supporting preparedness, response, and recovery efforts. Among the important reasons for the design and construction of such structures can be mentioned the centralization of operations, which specifies a multi-purpose hall provides a centralized place for CBRN operations, and the various resources, equipment, and personnel involved in the preparation, bring together CBRN response and recovery. It acts as a command center where decision-makers can effectively coordinate and manage activities and ensure a coordinated and effective response. In addition to training, the multi-purpose hall can serve as a dedicated place for CBRN training and exercises [1-4]. It provides a controlled environment where personnel can simulate and practice response procedures, test equipment and enhance their skills in handling CBRN incidents. Training and exercises conducted in the multi-purpose hall help ensure readiness and improve responsiveness. It can also be for proper storage, organization, and maintenance of CBRN equipment and supplies, which includes specialized protective equipment, detection and monitoring devices, disinfection equipment, and other essential tools used in CBRN incidents [5-7]. Having a designated place for equipment storage ensures quick access and proper care, minimizes response time, and optimizes equipment performance. Multipurpose halls for CBRN are equipped with decontamination facilities, including showers, washing stations, and appropriate disinfectant solutions. These facilities are critical for the rapid decontamination of people, equipment, and materials exposed to hazardous substances. Effective decontamination helps protect personnel, prevent cross-contamination, and maintain operational readiness. The multipurpose hall serves as a hub for communication and information sharing during CBRN incidents. It incorporates communication systems, command centers, and information management tools to facilitate real-time communication, coordination, and data exchange between response teams, external agencies, and other stakeholders. The important ones mentioned can support research and development efforts related to defense and CBRN technologies. They provide a controlled environment for testing and evaluating new equipment, protocols, and techniques for CBRN preparedness and response [8-10]. Research conducted at this center helps advance knowledge and improve CBRN capabilities. Also, its importance is in facilitating cooperation between different organizations involved in CBRN operations, where it brings together experts from different disciplines including emergency management, public health, law enforcement, and fire services, strengthening partnerships and increasing inter-agency coordination. This joint approach improves the effectiveness of response efforts and ensures a comprehensive and integrated response to CBRN incidents. Having a dedicated multi-purpose hall for CBRN operations demonstrates a commitment to public safety and preparedness. It instills confidence in the community by demonstrating the ability to effectively respond to CBRN incidents. The facility serves as a visible symbol of preparedness and preparedness, assuring the public that measures are in place to mitigate the risks associated with CBRN events [11-13].

Multipurpose halls are designed to accommodate a wide range of CBRN-related activities and can adapt to evolving needs and emerging threats. The versatility of the facility enables the integration of new technologies, the implementation of innovative approaches, and the ability to address a wide range of CBRN scenarios, ensuring the facility remains relevant and effective over time. The multipurpose hall provides a controlled environment for CBRN activities. It may have specialized ventilation and air filtration systems to prevent the release of hazardous agents, ensure personnel safety, and limit the impact of CBRN incidents. Facility design and infrastructure help contain CBRN materials and maintain a safe environment for operations [14-17].

MATERIALS AND METHODS

This research is qualitative research based on the content analysis method with a deductive and guided approach. A multipurpose hall for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes would need to be designed to accommodate various activities related to CBRN defense, response, and training. By studying and reviewing some sources including books, articles, and documents, some considerations for the design of such facilities were collected and reviewed as follows:

1. Location

The hall should be situated in a secure area away from densely populated areas, with easy access for emergency vehicles and personnel. The location of a multipurpose hall for CBRN (Chemical, Biological, Radiological, and Nuclear) activities is crucial and carries significant importance [18-20].

1.1. Safety and Security: The primary concern when dealing with CBRN hazards is the safety and security of personnel and the surrounding environment. Choosing an appropriate location away from densely populated areas helps minimize the risk of exposing a large number of people to potential CBRN incidents. It allows for better control, containment, and response to emergencies, reducing the potential for casualties and damage.

1.2. Proximity to Response Resources: The location of the hall should take into account its proximity to essential response resources, such as hospitals, emergency services, and specialized CBRN response teams. Being located within a reasonable distance of these resources enables faster and more efficient emergency response and medical assistance in case of an incident.

1.3. Access for Emergency Vehicles and Personnel: The hall should have suitable access points that allow easy entry and exit for emergency vehicles, such as ambulances and fire trucks. It should also provide convenient access for response personnel, enabling rapid deployment during emergencies. The location should consider factors like road infrastructure, transportation routes, and proximity to major highways or airports for logistical support.

1.4. Environmental Considerations: The location should take into account environmental factors that may affect the effectiveness of CBRN response operations. For instance, prevailing wind patterns, geographical features, and nearby bodies of water should be considered to assess the potential dispersion patterns of CBRN agents. This information helps in determining the best location to minimize the impact and spread of hazardous substances.

1.5. Zoning and Legal Requirements: Different jurisdictions may have specific zoning regulations and legal requirements for facilities handling CBRN materials. The location should comply with these regulations to ensure the facility's legality and appropriate adherence to safety protocols. Zoning restrictions may dictate areas suitable for CBRN-related activities, ensuring compatibility with neighboring properties and land use.

1.6. Training and Collaboration Opportunities: The location can also provide opportunities for collaboration and training with nearby CBRN response organizations, research institutions, or military installations. Proximity to such entities facilitates knowledge sharing, joint exercises, and the exchange of expertise, enhancing overall preparedness and response capabilities.

2. Structural Integrity

The building should be constructed to withstand potential CBRN incidents, including blasts and chemical or radiological hazards. Reinforced concrete walls and ceilings, as well as blast-resistant windows and doors, may be necessary. When designing a multipurpose hall for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes, ensuring the structural integrity of the facility is of utmost importance [21-24].

2.1. Robust Construction: The hall should be constructed using robust materials and techniques to withstand potential CBRN incidents. Reinforced concrete or other sturdy materials are commonly used for walls, floors, and ceilings. These materials provide strength and resistance to impacts, blasts, and structural damage.

2.2. Blast Resistance: The structure should be designed to resist the effects of explosions that may occur during CBRN incidents. This involves incorporating blast-resistant features, such as reinforced walls, windows, and doors. The design should consider blast loadings, shockwaves, and fragments, and ensure that the structure can withstand these forces without compromising its integrity.

2.3. Containment and Isolation: The hall should have the ability to contain and isolate CBRN hazards within designated areas. This can be achieved by using airtight seals, robust partitions, and barriers to prevent the spread of contaminants. The facility should also have separate zones to minimize cross-contamination and allow for efficient isolation of affected areas.

2.4. Protection from External Hazards: The design should consider potential external hazards that can impact the structural integrity, such as extreme weather events (e.g., hurricanes, earthquakes) or intentional attacks. Adequate measures, such as reinforced roofs, impact-resistant windows, and structural reinforcements, should be implemented to protect the facility from these external threats.

2.5. Structural Sealing: To prevent the ingress of CBRN agents, the hall should have a well-sealed structure. This includes ensuring tight seals around windows, doors, ventilation systems, and other openings. High-quality seals and gaskets should be used to maintain airtight integrity and prevent the infiltration of hazardous substances.

2.6. Access Points: The design should include controlled access points with appropriate security measures. These access points should be designed to withstand potential attacks or unauthorized entry attempts. Secure doors, locks, and surveillance systems should be employed to maintain the integrity of the facility.

2.7. Reinforced Utilities: Critical utilities, such as electrical systems, water supply, and HVAC (Heating, Ventilation, and Air Conditioning) systems, should be designed and positioned to withstand CBRN incidents. They may require additional reinforcement or protective measures to ensure continued operation during emergencies.

2.8. Structural Monitoring: Implementing structural monitoring systems can help detect and assess any potential structural vulnerabilities or damage. Structural sensors, such as strain gauges or vibration sensors, can be installed to monitor the health of the building and provide early warning of any compromised areas.

2.9. Compliance with Standards: The design should adhere to relevant building codes, safety regulations, and industry standards related to CBRN facilities. These standards ensure that the structural integrity meets specified requirements and guidelines for CBRN defense and response.

3. Ventilation and Filtration

The hall should have a robust ventilation system capable of providing a controlled airflow to prevent the spread of contaminants. High-efficiency air filtration systems, including HEPA filters, should be installed to remove CBRN agents from the air. Ventilation and filtration systems are critical components of a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes. They play a vital role in maintaining a safe and controlled environment by minimizing the spread of CBRN agents. [25-29].

3.1. Controlled Airflow: The hall should have a well-designed ventilation system capable of providing controlled airflow. This ensures that fresh air is supplied to occupied areas while maintaining appropriate pressure differentials to prevent the migration of CBRN agents to unaffected areas. The ventilation system should be designed with adjustable airflow rates to accommodate different scenarios and response requirements.

3.2. Air Filtration Systems: High-efficiency air filtration systems, including High-Efficiency Particulate Air (HEPA) filters, should be an integral part of the ventilation system. HEPA filters are highly effective in removing particulates, including biological agents, radioactive particles, and many chemical contaminants, from the air. These filters should be properly sized, installed, and maintained to ensure optimal filtration efficiency.

3.3. Filtration System Redundancy: Redundancy is crucial in CBRN facilities to ensure the continuous operation of filtration systems. The inclusion of backup or redundant filtration units and provisions for rapid filter replacement or change-out are important considerations. This helps maintain filtration performance in the event of filter saturation or system malfunctions.

3.4. Air Pressurization: In CBRN scenarios, it may be necessary to create areas with positive or negative air pressure to prevent the migration of CBRN agents. Positive pressure areas ensure that air flows out of the controlled area, reducing the risk of contaminants entering. Negative pressure areas draw air into the controlled area, preventing the release of hazardous agents to the outside environment. The ventilation system should be capable of maintaining the desired pressure differentials between different zones within the facility.

3.5. Isolation and Containment: The ventilation system should support isolation and containment measures during CBRN incidents. This can include the ability to seal off affected areas, establish differential pressure zones, and control airflow between different sections of the hall. These features help contain and prevent the spread of CBRN agents to unaffected areas.

3.6. Air Monitoring and Detection: Integrating air monitoring and detection systems into the ventilation system allows for continuous monitoring of air quality and the presence of CBRN agents. These systems can provide early warnings and trigger appropriate response actions if hazardous substances are detected. Air monitoring devices, such as gas detectors or biological sensors, should be strategically placed throughout the facility.

3.7. Maintenance and Monitoring: Regular maintenance, testing, and inspection of the ventilation and filtration systems are crucial to ensure their continued effectiveness. Filters should be replaced or cleaned at recommended intervals, and the functionality of the ventilation system, including airflow rates, pressure differentials, and alarms, should be regularly tested and verified.

3.8. Emergency Shutdown Procedures: The ventilation system should have emergency shutdown procedures in place to quickly stop airflow in case of emergencies or incidents. These shutdown procedures should be easily accessible and understood by authorized personnel to minimize the spread of CBRN agents during critical situations.

4. Decontamination Facilities

Dedicated decontamination areas should be included within the hall. These areas would typically have showers, washbasins, and appropriate decontamination solutions for individuals or equipment exposed to CBRN agents. Decontamination facilities are a crucial component of a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes. These facilities are necessary for the safe and effective decontamination of individuals and equipment that may have been exposed to CBRN agents [30, 31].

4.1. Showers and Washbasins: Dedicated areas with showers and washbasins should be included in the decontamination facility. These areas allow individuals to thoroughly wash their bodies, hair, and exposed skin to remove any contaminants. The showers should have an adequate water supply and temperature control to ensure effective decontamination.

4.2. Decontamination Solutions: The decontamination facility should provide appropriate decontamination solutions or agents to neutralize or remove CBRN agents from the skin, clothing, and equipment. These solutions should be selected based on the specific CBRN agents anticipated and their effectiveness in decontamination. Guidelines for the proper use and disposal of these solutions should be clearly provided.

4.3. Separate Areas for Contaminated and Clean Zones: The decontamination facility should have separate areas or designated zones for contaminated and clean areas to prevent cross-contamination. Individuals and equipment should enter the facility through the contaminated zone and proceed to the clean zone after decontamination.

4.4. Personal Protective Equipment (PPE): Adequate storage space should be provided within the decontamination facility for storing personal protective equipment (PPE) used during the decontamination process. This includes items such as gloves, masks, goggles, and disposable suits. The storage area should be easily accessible and well-organized for quick retrieval of PPE.

4.5. Waste Management: Proper waste management procedures should be in place to handle and dispose of contaminated waste generated during the decontamination process. This may include designated waste collection containers, hazardous waste disposal protocols, and compliance with local regulations and guidelines for waste management.

4.6. Water Drainage and Containment: The decontamination facility should have appropriate water drainage and containment systems to prevent the spread of contaminants. This includes the installation of floor drains, impervious flooring, and adequate water collection and containment mechanisms to prevent the runoff of contaminated water into other areas.

4.7. Accessibility and Safety: The decontamination facility should be designed to be accessible to individuals with disabilities and consider their specific needs during the decontamination process. Additionally, safety measures such as slip-resistant flooring, proper lighting, and emergency communication systems should be in place to ensure the safety of individuals using the facility.

4.8. Training and Procedures: Clear operating procedures and training materials should be developed and provided to personnel using the decontamination facility. This includes instructions on proper decontamination techniques, the sequence of actions, handling of equipment, and safety protocols to ensure effective decontamination and minimize the risk of recontamination.

4.9. Maintenance and Inspection: Regular maintenance, inspection, and testing of decontamination facilities are essential to ensure their continued functionality and compliance with safety standards. This includes routine checks of water supply, showers, drainage systems, PPE storage, and decontamination solutions to verify their effectiveness and readiness for use.

5. Equipment Storage

Adequate storage space should be provided to house CBRN-related equipment, such as personal protective equipment (PPE), detection devices, decontamination supplies, and specialized response tools. Equipment storage is a critical aspect of a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes. Proper storage facilities are essential for organizing and safeguarding CBRN-related equipment, ensuring readiness and quick access when needed [32-35].

5.1. Dedicated Storage Areas: Designate specific areas within the multipurpose hall for equipment storage. These areas should be easily accessible and organized, allowing for efficient retrieval and inventory management. Depending on the size and quantity of equipment, different storage options such as cabinets, shelves, lockers, or specialized storage racks may be utilized.

5.2. Equipment Categorization: Categorize CBRN equipment based on its type, purpose, and level of protection. This helps in organizing and locating items quickly during emergencies or training exercises. For example, respiratory protection equipment, protective suits, detection devices, decontamination supplies, and specialized response tools may each have their designated storage area or section.

5.3. Secure Storage: Implement appropriate security measures to ensure the integrity and protection of stored equipment. This may include restricted access to storage areas, lockable cabinets or containers, surveillance systems, and inventory control protocols. Access should be limited to authorized personnel only, minimizing the risk of theft, tampering, or unauthorized use.

5.4. Equipment Maintenance: Provide space and resources for equipment maintenance, cleaning, and inspection within the storage area. This includes workbenches, tools, cleaning agents, and dedicated areas for equipment servicing. Regular maintenance ensures that the equipment remains in good working condition and is ready for use when needed.

5.5. Proper Ventilation: Ensure adequate ventilation within the storage area to prevent the buildup of moisture, humidity, or other environmental factors that may damage the equipment. Proper airflow helps maintain the longevity and functionality of sensitive equipment, especially when stored for extended periods.

5.6. Labeling and Inventory Management: Clearly label storage areas and equipment to facilitate easy identification. Implement an inventory management system that tracks the location, condition, and usage of equipment. This enables efficient inventory control, timely replacement of expired or damaged items, and ensures readiness during CBRN incidents or training exercises.

5.7. Compliance with Safety Regulations: Ensure compliance with safety regulations and guidelines for the storage of CBRN-related equipment. These regulations may include specific requirements for hazardous materials, controlled substances, or sensitive equipment. Adhering to these regulations promotes safety, minimizes risks, and maintains legal compliance.

5.8. Training and Familiarization: Provide appropriate training and familiarization to personnel on the location, access procedures, and handling protocols for stored CBRN equipment. This ensures that authorized personnel are knowledgeable about the equipment, understand its usage, and can retrieve or store it safely.

5.9. Emergency Preparedness: Develop emergency response plans that outline procedures for accessing and utilizing stored CBRN equipment during emergencies. This includes provisions for quick retrieval, distribution, and deployment of equipment to relevant personnel or response teams.

5.10. Regular Audits and Inspections: Conduct regular audits and inspections of the equipment storage areas to ensure compliance, proper organization, and readiness. This involves checking expiration dates, conducting inventory reconciliation, and assessing the overall condition of the stored equipment.

6. Training and Simulation

The hall should offer versatile training capabilities, including simulation scenarios for CBRN incidents. This may involve the use of specialized training props, mock environments, and immersive simulation technologies. Training and simulation capabilities are vital components of a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes. These features allow personnel to acquire the necessary knowledge, skills, and experience in a controlled environment to effectively respond to CBRN incidents [32, 36-41].

6.1. Training Areas: Designate specific areas within the multipurpose hall for training exercises. These areas should be versatile and adaptable to simulate different CBRN scenarios, such as mock incident sites, contaminated zones, or confined spaces. The layout and features of these areas can be modified to replicate real-life scenarios and provide a realistic training environment.

6.2. Simulation Tools: Incorporate various simulation tools and equipment to enhance training effectiveness. This may include smoke generators, simulated hazardous substances, training mannequins, or specialized props that mimic CBRN hazards. The use of these tools helps create realistic scenarios, enabling trainees to practice response procedures and decision-making skills.

6.3. Training Props and Equipment: Provide training props and equipment that replicate actual CBRN response gear, including personal protective equipment (PPE), detection devices, decontamination equipment, and specialized response tools. These props should closely resemble the functionality and characteristics of real equipment, allowing trainees to become familiar with their use and limitations.

6.4. Emergency Communication Systems: Install reliable emergency communication systems throughout the training areas to facilitate coordination and communication between trainees, instructors, and control personnel. These systems may include intercoms, radios, or other communication devices that mimic real-world communication protocols used during CBRN incidents.

6.5. Monitoring and Feedback: Incorporate monitoring systems to capture trainees' actions, responses, and performance during training exercises. This may involve video recording, sensors, or observation booths for instructors to assess trainee actions and provide feedback. Monitoring and feedback play a crucial role in identifying areas for improvement and enhancing trainee proficiency.

6.6. Training Scenarios and Drills: Develop a variety of realistic training scenarios and drills that cover different aspects of CBRN incidents, such as detection, containment, decontamination, and response protocols. These scenarios should be designed to challenge trainees' knowledge and skills progressively, allowing them to practice different response strategies and experience various levels of complexity.

6.7. Safety Protocols: Implement strict safety protocols during training exercises to minimize risks to trainees and instructors. This includes setting clear safety guidelines, conducting risk assessments, and providing appropriate personal protective equipment. Safety measures should be strictly enforced to ensure the well-being of all participants during training activities.

6.8. Training Curriculum and Instructors: Develop a comprehensive training curriculum that covers theoretical knowledge, practical skills, and decision-making exercises related to CBRN incidents. The curriculum should be designed to cater to different levels of expertise, ranging from basic awareness to advanced response techniques. Qualified instructors with relevant expertise in CBRN defense and response should lead the training sessions.

6.9. After-Action Reviews: Conduct after-action reviews following each training exercise or drill to evaluate performance, identify strengths and areas for improvement, and facilitate continuous learning. These reviews should involve all participants, including trainees, instructors, and control personnel, to gather valuable feedback and insights for future training enhancements.

6.10. Integration with Emergency Response Plans: Ensure that the training and simulation activities align with established emergency response plans and procedures. This integration helps familiarize trainees with the actual protocols and coordination mechanisms that would be used during real CBRN incidents, enhancing overall preparedness and effectiveness.

7. Communication Systems

Robust communication infrastructure, including radio systems, internet connectivity, and intercoms, should be integrated into the facility to support coordination during emergencies. Effective communication systems are essential in a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes. These systems enable efficient coordination, information sharing, and emergency response during CBRN incidents [42-44].

7.1. Intercom Systems: Install intercom systems throughout the multipurpose hall to facilitate direct communication between different areas, such as control rooms, training areas, storage facilities, and decontamination zones. Intercoms allow for quick and clear communication, enabling effective command and control during CBRN incidents.

7.2. Two-Way Radios: Equip personnel with two-way radios to enable real-time communication between individuals or teams within the multipurpose hall. Two-way radios provide mobile communication capabilities, allowing personnel to stay connected while moving within the facility. Ensure that the radio system has sufficient coverage within the hall and is compatible with existing communication infrastructure.

7.3. Emergency Broadcast Systems: Implement emergency broadcast systems that can disseminate critical announcements, instructions, or alerts to all personnel within the multipurpose hall. These systems can include loudspeakers strategically positioned throughout the facility, enabling mass notification and ensuring that important information reaches all occupants, even in noisy or crowded environments.

7.4. Digital Communication Platforms: Utilize digital communication platforms, such as email, instant messaging, or mobile applications, to enhance communication and information sharing among personnel. These platforms can be particularly useful for non-emergency situations, such as routine updates, scheduling, or sharing documents related to CBRN operations.

7.5. Video Conferencing: Integrate video conferencing capabilities into designated areas, such as command centers or control rooms, to facilitate remote communication and coordination with external stakeholders or off-site experts. Video conferencing allows for real-time visual communication, enabling efficient collaboration and decision-making during CBRN incidents.

7.6. Data and Network Connectivity: Ensure reliable data and network connectivity throughout the multipurpose hall to support effective communication. This includes providing sufficient Wi-Fi coverage, Ethernet ports, and network infrastructure to facilitate the use of communication devices, access to online resources, and data exchange among personnel.

7.7. Emergency Communication Protocols: Establish clear emergency communication protocols and procedures for CBRN incidents. These protocols should outline communication chains of command, designated emergency communication channels, and reporting mechanisms. Ensure that personnel are trained on these protocols and familiar with the appropriate use of communication systems during emergencies.

7.8. Integration with External Communication Networks: Coordinate with external emergency response agencies, such as fire departments, law enforcement, or medical services, to integrate the multipurpose hall's communication systems with their networks. This allows for seamless communication and coordination during joint response efforts or when seeking external assistance.

7.9. Backup Power and Redundancy: Implement backup power systems, such as uninterruptible power supplies (UPS) or emergency generators, to ensure communication systems remain operational during power outages or emergencies. Additionally, consider redundancy in communication systems to minimize the risk of single points of failure and maintain continuous communication capabilities.

7.10. Testing and Maintenance: Regularly test and maintain communication systems to ensure their reliability and functionality. Conduct periodic drills or simulations to validate the effectiveness of communication systems during various scenarios. Routinely check equipment, perform system checks, and update software or firmware to address any vulnerabilities or issues.

8. Safety Systems

The hall should be equipped with safety features, such as emergency alarms, evacuation routes, emergency lighting, and fire suppression systems, to ensure the safety of personnel during CBRN incidents. Safety systems play a crucial role in ensuring the protection of personnel and minimizing risks in a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes [42-50].

8.1. Fire Suppression Systems: Install fire suppression systems, such as sprinklers or specialized suppression agents, throughout the multipurpose hall. These systems should be designed to quickly detect and suppress fires, minimizing the risk of fire-related incidents. Ensure that the fire suppression systems are compatible with the CBRN activities and do not pose additional risks during CBRN incidents.

8.2. Emergency Lighting: Implement reliable emergency lighting systems that automatically activate during power outages or emergencies. Emergency lighting helps maintain visibility, especially in areas critical for evacuation or emergency response. Ensure that emergency lighting is strategically placed to illuminate evacuation routes, exits, and important safety equipment.

8.3. Emergency Power Backup: Provide emergency power backup systems, such as uninterruptible power supplies (UPS) or emergency generators, to ensure essential safety systems remain operational during power failures or emergencies. Critical systems, including emergency lighting, communication systems, fire suppression systems, and ventilation, should be connected to the emergency power backup.

8.4. Alarm Systems: Install comprehensive alarm systems that include audible and visual alarms throughout the multipurpose hall. These alarms should be triggered automatically in the event of CBRN incidents, fires, or other emergencies, alerting personnel to take appropriate actions. Consider integrating the alarm systems with the overall facility's alarm system to ensure a coordinated response.

8.5. Ventilation and Air Filtration Systems: Implement robust ventilation and air filtration systems designed to handle CBRN contaminants. These systems should be capable of providing a continuous supply of fresh air, removing airborne contaminants, and controlling the circulation of hazardous substances. Regular maintenance and filter replacement should be carried out to ensure their effectiveness.

8.6. Emergency Evacuation Plans: Develop and communicate clear emergency evacuation plans for the multipurpose hall. These plans should include designated evacuation routes, assembly points, and procedures for personnel to follow during CBRN incidents or other emergencies. Display evacuation maps prominently throughout the facility and conducts regular drills to familiarize personnel with evacuation procedures.

8.7. Personal Protective Equipment (PPE): Ensure that an adequate supply of appropriate personal protective equipment (PPE) is readily available throughout the multipurpose hall. This includes respiratory protection, protective clothing, gloves, goggles, and other necessary equipment for personnel to protect themselves during CBRN incidents or when handling hazardous substances.

8.8. Emergency Response Equipment: Equip the multipurpose hall with emergency response equipment such as first aid kits, stretchers, eye wash stations, and emergency showers. These provisions ensure that immediate medical attention can be provided in case of injuries or exposure to hazardous substances. Regularly check and replenish the emergency response equipment as needed.

8.9. Safety Signage: Install clear and visible safety signage throughout the multipurpose hall. This includes signs indicating the location of emergency exits, first aid stations, fire extinguishers, hazardous material storage areas, and other critical safety equipment. The signage should use internationally recognized symbols and be easily understandable in high-stress situations.

8.10. Safety Training and Education: Provide comprehensive safety training and education programs for all personnel working in the multipurpose hall. This includes CBRN safety protocols, proper use of safety equipment, evacuation procedures, and the recognition of potential hazards. Regularly refresh and update training programs to ensure personnel are well-prepared and informed.

9. Accessibility

The facility should be designed to accommodate individuals with disabilities and provide ease of access for emergency responders and equipment. Ensuring accessibility in a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes is important to accommodate individuals with disabilities or mobility challenges [51-54].

9.1. Accessibility Standards: Adhere to local accessibility standards and regulations when designing and constructing the multipurpose hall. These standards typically outline requirements for ramps, door widths, corridor widths, accessible parking spaces, and other accessibility-related features. Compliance with these standards promotes inclusivity and provides equal access for all individuals.

9.2. Ramps and Elevators: Install ramps or elevators at entrances and other areas with level changes to ensure wheelchair users and individuals with mobility aids can access different parts of the facility. Ramps should be designed with appropriate slopes, handrails, and tactile indicators to enhance safety and usability.

9.3. Accessible Parking Spaces: Designate accessible parking spaces near the entrance of the multipurpose hall. These spaces should be wide enough to accommodate accessible vehicles and provide sufficient clearance for wheelchair users to enter and exit the vehicles comfortably. Accessible parking spaces should also be conveniently located and clearly marked.

9.4. Wide Doorways and Corridors: Ensure that doorways and corridors within the multipurpose hall are wide enough to accommodate individuals using wheelchairs or mobility aids. The minimum width should comply with accessibility standards to allow for easy passage and maneuverability. Install automatic doors or door openers where feasible to facilitate independent access.

9.5. Accessible Restrooms: Provide accessible restrooms that meet the requirements of accessibility standards. These restrooms should have appropriate door widths, grab bars, accessible sinks, and other necessary features to ensure usability for individuals with disabilities. Signage indicating the location of accessible restrooms should be clearly visible.

9.6. Tactile and Visual Cues: Incorporate tactile and visual cues throughout the multipurpose hall to assist individuals with visual impairments or hearing impairments. This may include braille signage, tactile floor indicators, contrasting colors for wayfinding, and visual alarms or flashing lights for emergency notifications.

9.7. Seating Arrangements: Plan seating arrangements within the multipurpose hall to accommodate individuals with disabilities. Ensure that there are designated spaces for wheelchair users, as well as companion seating options for individuals with disabilities attending events or training sessions.

9.8. Assistive Listening Devices: Provide assistive listening devices, such as induction loop systems or FM systems, to assist individuals with hearing impairments during presentations, meetings, or training sessions. These devices transmit audio directly to compatible hearing aids or personal receivers, improving sound clarity and accessibility.

9.9. Training and Awareness: Train staff and personnel on disability awareness, including best practices for assisting individuals with disabilities and addressing their specific needs. Sensitize employees on the importance of inclusive practices and provide them with the knowledge and skills to ensure a welcoming and accessible environment.

9.10. Continuous Evaluation and Improvement: Regularly assess the accessibility features and gather feedback from individuals with disabilities or accessibility experts. Identify areas for improvement and implement necessary modifications to enhance accessibility in the multipurpose hall. This may include adjusting door widths, adding additional signage, or addressing any barriers that may impede accessibility.

10. Security Measures

Strict security measures should be implemented to prevent unauthorized access to CBRN materials and ensure the facility's integrity. Implementing robust security measures in a multipurpose hall designed for CBRN (Chemical, Biological, Radiological, and Nuclear) purposes is crucial to protect personnel, prevent unauthorized access, and safeguard sensitive materials and equipment [51, 55-59].

10.1. Perimeter Security: Establish a secure perimeter around the multipurpose hall to control access and deter unauthorized entry. This may include fencing, gates, access control systems, surveillance cameras, and signage indicating restricted access. Implement measures to monitor and control vehicle and pedestrian access points.

10.2. Access Control Systems: Install access control systems at entry points to regulate and monitor personnel entering and exiting the multipurpose hall. This can include electronic key card systems, biometric readers, or other secure authentication methods. Access control systems enable authorized personnel to enter while restricting access to unauthorized individuals.

10.3. Video Surveillance: Deploy a comprehensive video surveillance system throughout the multipurpose hall. Install high-quality cameras in strategic locations, including entrances, exits, critical areas, storage facilities, and external perimeters. Monitor and record video footage to deter potential security breaches and assist in investigations if necessary.

10.4. Intrusion Detection Systems: Implement intrusion detection systems, including motion sensors, door/window sensors, and glass break detectors, to detect and alert security personnel about any unauthorized access attempts or suspicious activities within the multipurpose hall. Integrate these systems with the overall security infrastructure for a prompt response.

10.5. Security Personnel: Assign trained security personnel to monitor and patrol the multipurpose hall. They should be responsible for enforcing security policies, performing regular security checks, responding to alarms, and maintaining a visible security presence. Security personnel should be adequately trained in CBRN security protocols and emergency response procedures.

10.6. Restricted Areas: Designate specific areas within the multipurpose hall as restricted zones, accessible only to authorized personnel with appropriate security clearance. Use physical barriers, access control systems, or biometric authentication to ensure limited access to sensitive areas, such as storage facilities, control rooms, or laboratories.

10.7. Alarm and Alert Systems: Install audible and visual alarm systems throughout the multipurpose hall to notify personnel of emergencies, security breaches, or CBRN incidents. These systems should be interconnected and capable of providing specific alerts and instructions based on the nature of the incident.

10.8. Cybersecurity Measures: Implement robust cybersecurity measures to protect digital systems, networks, and sensitive information within the multipurpose hall. This includes firewalls, secure authentication protocols, regular software updates, data encryption, and employee awareness training on cybersecurity best practices. Protecting digital assets is crucial to prevent unauthorized access or manipulation of critical information.

10.9. Incident Response Plan: Develop a comprehensive incident response plan that outlines procedures and protocols to address security incidents, including CBRN-related events. The plan should cover roles and responsibilities, communication protocols, evacuation procedures, and coordination with external emergency response agencies. Regularly review and update the plan to reflect changing security needs and emerging threats.

10.10. Training and Awareness: Conduct regular security training sessions for all personnel working in the multipurpose hall. This should include CBRN security awareness, identification of suspicious activities, proper use of access control systems, and response to security incidents. Regularly reinforce security practices and encourage personnel to report any security concerns promptly.

RESULTS

The location of a multipurpose hall for CBRN activities significantly impacts the safety, response efficiency, accessibility, compliance with regulations, and collaboration opportunities. Careful consideration of these factors during the selection process ensures that the facility is strategically positioned to mitigate risks and effectively respond to CBRN incidents.

By incorporating these considerations, a multipurpose hall for CBRN purposes can be designed to provide a structurally sound and resilient environment that can withstand CBRN incidents and protect occupants from potential hazards. It is important to consult with structural engineers and professionals experienced in CBRN facility design to ensure compliance with safety standards and best practices.

Other important points are consulted with ventilation and filtration experts, as well as professionals with expertise in CBRN defense and response, to design and install appropriate systems that meet safety standards and requirements specific to your location and the intended use of the multi-purpose hall.

Experts have an important role in decontamination procedures, CBRN defense, and response when designing and implementing decontamination facilities. They can guide best practices, safety standards, and compliance with local regulations to ensure the decontamination facility meets the specific requirements for CBRN-related activities in the multipurpose hall.

The equipment storage in a multipurpose hall for CBRN purposes can be efficiently organized, secure, and readily accessible. Consulting with CBRN defense and response experts can provide valuable insights and guidance on specific storage requirements, safety protocols, and best practices.

A multipurpose hall for CBRN purposes can provide a realistic and effective training environment. It is crucial to collaborate with CBRN defense and response experts, experienced instructors, and relevant stakeholders to design and implement a comprehensive training and simulation program that meets specific training objectives and regulatory requirements.

A multipurpose hall for CBRN purposes can establish robust communication systems that enable effective coordination, information sharing, and emergency response. It is important to consult with communication experts and incorporate best practices specific to CBRN operations to ensure the implementation of reliable and efficient communication capabilities.

It is crucial to consult with safety experts, regulatory guidelines, and CBRN defense professionals to ensure the implementation of appropriate safety systems in the multipurpose hall. Regular inspections, maintenance, and adherence to safety regulations are essential to maintain a safe environment for personnel involved in CBRN activities.

A multipurpose hall for CBRN purposes can be designed to provide equal access and inclusion for individuals with disabilities or mobility challenges. Collaboration with accessibility experts and engaging individuals with disabilities during the design process can offer valuable insights and ensure that the facility meets its specific needs.

DISCUSSION

Creating a multi-purpose hall that is specifically designed for CBRNE incidents is necessary for several reasons, such as: having a dedicated facility, the possibility of a centralized response to CBRNE incidents, the need for CBRNE incidents to have specialized infrastructure and facilities to manage the unique challenges caused by Chemical, biological, radiological, nuclear and explosive risks.

Provide a dedicated controlled environment theater for training and preparedness activities where responders can simulate CBRNE incidents, practice response methods, test equipment, and coordinate between different agencies and organizations. improve Regular training exercises in a realistic environment to enhance preparedness and enable responders to develop the skills and knowledge necessary to effectively manage CBRNE incidents. Many other reasons are given in this study, in addition to the description of the necessity of building such structures, which deals with the detailed study of the required factors in order to be used as a minimum checklist for the establishment and creation of such multi-purpose halls.

Consequently, a multi-purpose theater designed specifically for CBRNE incidents, due to its ability to centralize response efforts, provide specialized infrastructure, facilitate training and preparedness, support decontamination and treatment, encourage research and development, enhance safety public, and promote cooperation between stakeholders is essential. Such facilities will significantly improve the overall response to CBRNE incidents and increase the resilience of communities to these complex and dangerous events.

Abstract: *Background: The effect of stress on sympathetic modulation measured by HRV has been studied in various population groups exposed to different stressors. HRV measurement tools are based on the electrocardiogram (ECG), portable tools such as POLAR V800, and recently photoplethysmography (PPG). The aim of this study was to analyze the validity of a PPG mobile app to measure HRV with a validated V800 system in a tactical athlete population. Methods HRV of 53 professional militaries were analyzed by POLAR V800 and an HRV Camera app with a smartphone during 5 min and 30 s protocol respectively. Results: The HRV values obtained by the PPG presented a significant negative significant correlation in the HRVI index, LF, HF, LF (n.u.), HF (n.u.), and a positive significant correlation in TINN index by the Polar V800 system with the application of a regression equation over the data obtained. Conclusions: HRV Camera PPG App 30s record analysis protocol could be applied using a regression formula depending on the HRV variables after the comparison with a standard 5-minute test conducted with a validated Polar V800. In future research, it is suggested to validate PPG protocols with longer durations.*

Keywords: *Heart rate variability, military, autonomic modulation, photoplethysmography*

INTRODUCTION

Heart rate variability (HRV) represents the physiological response of the variation in the interval of time between each heartbeat. It is measured by the variation in the interval from beat to beat [1]. This modulation is controlled by the balance between the activation of the Parasympathetic Nervous System (PNS), and Sympathetic Nervous System (SNS) which is named autonomic modulation [2]. This physiology response is related to the effect of the stress or to exposure to stressors agents due to experiences or the type of work performed, [3] showing a variation in HRV variables that is related to a low parasympathetic activity, which is characterized by an increased sympathetic activity [1].

The effect of stress on sympathetic modulation measured by HRV has been studied in various population groups exposed to different stressors as ultra-endurance athletes [4], skydivers [5], firefighters [6], policemen [7], soldiers [8], pilots [9], journalists [10], students [11], professors [12], and sanitary [13]. Independently of the population, an increased sympathetic modulation was observed when they were exposed to the stressor, a fact related to the activation of the fight-flight response [14]. The fight or flight response is a psychophysiological reaction that is produced by the presence of a threat, in which the body responds by activating the sympathetic nervous system (SNS) and the adren-al-cortical system [15]. Military personnel, due to their duty and the exigences of their operation are considered tactical athletes and are a clear example of a high-stress exposure population group. Previous research found a high activation of the SNS in melee combat simulations [16], as well as in asymmetrical [17] and urban combat [14]; the organic response was also evaluated in light infantry and heavy infantry in combat simulations [18].

Along the same line, HRV measurement can be an efficient device to understand the state of the autonomic nervous system in sports athletes, which showed changes in their HRV and stress level due to the stress that competition can produce [19]. In this way, HRV should be a tool to avoid the state of overload of the athlete, and at the same time provide us with how the state of an athlete and ad equating a control of the workout loads [20,21].

HRV measurement tools are based on the electrocardiogram (ECG) analysis which has proven effective for stress detection [22]. There are also portable tools such as the POLAR V800 heart rate monitor that showed its effectiveness to evaluate HRV and stress response [23,24]. Recently there are new tools such as photoplethysmography (PPG), which could be an alternative evaluation tool to the ECG and heart rate monitors. Previous studies showed how PPG could be an alternative to evaluated HRV signal in ECGs derivation and analysis in ambulatory cardiac monitoring of healthy individuals [25–27]. This kind of tool is proven in new technologies such as smartphones as fingertip recording mobile-app where there are some researchers that tested this kind of technology as a useful tool [28–31].

New technologies as smartphones or smartwatches, could be an interesting tool for the military who work in austere environments and are already familiar with the use of these devices. There are actually applications of weather impact in military corps [32], prototypes of military medical applications for combat medics and other health care providers [33], a behavioral health screening app [34] or tools for posttraumatic stress diseases [35], but not to analyze the acute autonomic status of this personnel. Then, the aim of this study was to analyze the validity of a PPG mobile app to measure HRV with a validated V800 system in a tactical athlete population. The initial hypothesis was that PPG mobile app would be a valid system to analyze HRV compared with a validated V800 system.

MATERIALS AND METHODS

53 professional military of the Spanish Army (age: M = 35.4 years, SD = 5.88 years; height: M = 174.89 cm, SD = 6.87 cm; body mass: M = 77.33 kg, SD = 11.95 kg; Military Duty= 14.44years, SD=6.43; Military Operation= 4 months, SD= 4.25 months) were analyzed. Procedures and protocols were explained to all the subjects who gave the voluntary written informed in accordance with the Declaration of Helsinki and approved by the European University Ethics Committee (CIPI/18/093).

HRV was measured by a validated Polar V800 heart rate monitor (Polar, Kempele)[36] and the PPGV mobile app for Android HRV by Camera. For this aim the Polar electrode belt was placed following Polar's guidelines in the middle of the chest. Then, participants remained seated for 5 minutes in a quiet room while the Polar V800 record the signal minutes before a maneuver meeting. After 2 minutes of starting recording, they place the index finger in the camera of a mobile device following the guideline of the HRV by Camera ECG Android App supported for BLE devices in order to analyze the HRV PPG based. The PPGV analysis lasted 30 seconds in which the participant remained sited, with the right arm flexed at 90º supported in an armrest.

The following HRV variables were obtained by the two devices:

Mean R-R; the standard deviation of successive differences (SDNN); mean HR; root mean square of successive differences (RMSSD); the number of adjacent intervals varying by more than 50ms (PNN50); HRV triangular index (HRVI); interval histogram (TINN); low-frequency power (LF); high-frequency power (HF); the low-frequency band in normalized units (LFun); the high-frequency band in normalized units (HFun); the sensitivity of the short-term variability (SD1) and the sensitivity long-term variability (SD2).

Statistical analysis

The SPSS statistical package (version 21.0; SPSS, Inc. Chica-go, Illinois) was used to analyze the data. Normality assumptions were checked with a Kolmogorov-Smirnov test. It evaluated an Intra-class Correlation (ICC) and 95% Confidence Interval (CI), Pearson correlation, and a regression equation. The level of significance for all the comparisons was set at $P < 0.05$.

RESULTS

The results are reported with their mean and standard deviation. Table 1 shows the results of HRV for each test. A negative significant correlation was found in HRVI, LF, HF, LF(n.u.), HF (n.u.) values. Also was found a significant positive correlation in TINN values. No correlations were found between other parameters.

DISCUSSION

Authors should discuss the results and how they can be interpreted from the perspective of previous studies and of the working hypotheses. The findings and their implications should be discussed in the broadest context possible.

Future research directions may also be highlighted.

CONCLUSION

The aim of this study was to analyze the validity of a PPG mobile app to measure HRV with a validated polar V800 system in the athlete population. The initial hypothesis was partially fulfilled since some PPG mobile app values presented positive and negative correlations than a validated V800 system.

HRV measurement is an efficient and important approach to assess autonomic modulation, which shows the stress state of the organism [37].

Table 1: This is a table.

	Polar		HRV Camera		ICC (CI 95%)	Pearson	Regression	p

M: Mean. SD: Standard Deviation. F: Fisher-Snedecor test. ICC: Intraclass correlation. SDNN: Standard deviation of normal-to-normal R-R intervals. RMSSD: Square root of the mean of the sum of the squared differences between adjacent normal R-R intervals. pNN50: The percentage of differences between R-R intervals higher than 50 ms.HRVI: HRV triangular index. TINN: interval histogram. LF: Low frequency. HF: High frequency. n.u.: Normalised unit. SD1: Poincaré Plot index of instantaneous recording of the variability. SD2: Poincaré plot index of overall variability.

The benefits of evaluating heart rate variability have been observed in psychological disorder as depression and posttraumatic stress disorder [38] and other medical diseases that are accompanied by a dysregulation of the autonomic nervous system such as asthma, heart failure, or hypertension [39]. The utility in sports has been also demonstrated due to the organic alterations suffered by athletes performing physical training. In this line, HRV has been shown as an efficient tool to control the athlete's internal load as a stress marker [40], being useful in designing conditioning programs that ensure a sufficient load that corresponds to the specific capacity of the athlete [21] and prevent states of overload and fatigue of the athlete [21].

HRV measurements have been also used to evaluate the anxiety level of the military population[41,42]. In this line, we found similitudes between soldiers' RMSSD PPG smartphone app values and values of non-elite soldiers found in previous research (44.64 ± 20.10 ms and 41.82 ± 22.95 ms respectively) [43]. In this line, we found RMSSD similar values in military pilots in repose (44.28 ± 25.96 ms) where could be similar HRV response due to stressors before a military operative flight training [44]. Although, it is observed lower RMSSD results than helicopter flight-fighter before a night maneuver (93.4±71.1 ms) [9] and some higher than military corps before underwater evacuation training (33.11 ± 18.73 ms)[45]. Regarding the behavior of this parameter in other athletes. It is observed higher values in athletes in the competition period (61.8 ± 51.73 ms)[46] which indicate that the similarity of RMSSD values in different scenarios is not an exact predictive.

Regarding other PPG system values, we found similar results in the LF values (n.u.) with Special Operation soldiers population in basal conditions before a military operation maneuver (60.94 ± 87.55 vs 60.61 ± 6.66 respectively) [47]. Similar results were shown by a rescue helicopter crew before a flight maneuver (63.6 ± 21.5) [48]. In this line, it has found similarities as athletes in the competition period (64.2 ± 18.70) [46]. Although all cases showed a standard deviation minor than showed in this investigation it presented a similar response in basal conditions before exposure to stressors.

The great contrasts in the frequency values also are observed if we compare to previous literature in basal LF values (740.03 ± 1207.76 vs 64.44 ± 18.00) and basal HF values (426.49 ± 417.62 vs 35.49 ± 18.01) in pilots before a real and simulated flight maneuver [44]. This large discrepancy in the LF and HF values could be produced by an error in the measurement procedure of the mobile app.

In this line, other values in basal conditions show differences compared to previous research, such as the mean RR values, which we observed lower values than thirty-one male subjects from the Spanish Army prior to simulated combat (941.37±165.15 vs 872.8±150.4) [49]. This discrepancy of responses showed in the HRV values in basal conditions may not be produced by the stressor that the subject will face, if not by the difference of subject experience or research protocols.

A disagreement is also observed in the HRV values obtained by the PPG mobile application compared to those obtained with the validated Polar V800 tool. We found a discrepancy to the values obtained by the Polar V800 system where, there was a large discrepancy in the LF values (740.03 ± 1207.76 vs 74.22 ± 14.73 respectively), HF values (426.49 ± 417.62 vs 25.7± 214.71 respectively). The disparity in the HRV data analyzed in our investigation could be due to the APP's short-time analysis protocol, of 30 seconds. This duration was selected in order to find the protocol that would require the least time from the participants due to the low availability of time in the measured population, trying to find the most efficient protocol and enough time to provide HRV measurements as the application sentence. The protocol of the Polar V800 system was 5 minutes, which is more reliable due to the duration of the measurement, which is similar to those seen in the rest of the protocols in investigations with other PPG technology devices.

On the contrary, to solve the discrepancy in the data, the application of a regression equation produces the correlation of the values. Positive and negative correlations in frequency values, HRVI index, and TINN index have been observed between both devices. In this case, the PPG system could provide us with reliable results in a short time record.

This fact is related to previous research that validated different PPG tools with standard systems such as HRV4Training [31] which has been proven a systematic tool to measure to optimize individualized training in professional endurance runners [50] and cyclists [51]. This kind of app delivers efficient results comparable to the ECG for measuring HRV in basal conditions where measurements protocols consisted at least of a 1 min recording [52]. Therefore, there could be greater efficiency in terms of HRV recording as long as the measurement time is greater than that proposed in our research without the need to apply any type of equation.

The evaluation and measurement of HRV have also been evaluated in PPG technology in other devices such as wristband devices. It has been demonstrated satisfactory HRV-related mental stress prediction taking LF/HF feature and with a similar record protocol as our research, 30 seconds of registration, but in this case with more records, three times per day in wristband PPG device [53]. In addition, the Apple Watch showed a significant decrease in values related to increased stress, HF, and RMSSD, with a protocol of 2 sets of 5 minutes [54] and Wrist-Worn Polar Vantage V2 PPG which is regarded as an HRV PPG system record efficient in athletic and healthy population with long time period protocols,7 minutes in supine position in a laboratory and 4 hours recording period during nocturnal sleep time [55]. Showing in all the cases better results when the measurement time is longer in time or with several records in a period of time.

Practical application

Present results joining other research could help refine an exact protocol for using the PPG smartphone apps, and become an effective and easy-to-use tool in harsh conditions. And provide us with the correlation equation for the validity of the data obtained through this application with a protocol with a short time record.

Limitations of the study and future research lines

The main limitation of this study is the low sample of participants. Also, it could be recommended the use of ECG to compare values as in previous research. In future research, it is suggested to validate PPG protocols with longer durations.

Abstract: *Clostridium difficile infection (CDI) is one of the most common healthcare-associated infections and an important cause of morbidity and mortality worldwide. The objective of the study was to identify the predictive factors for unfavorable evolution and deaths among patients with CDI. Materials and methods: We conducted a retrospective, observational, non-randomized study on 202 patients diagnosed with CDI in the Clinical Emergency Hospital of Bucharest, Romania, for a period of two years. For the statistical analysis, the R program was used, with p-values <0.05 being considered statistically significant. Results: The average age of the patients included in the study was 70.8 years, the average duration of hospitalization was 18.4 days, and the mortality rate was 25.7%. During the follow-up period, only 5% of the patients presented a recurrence of CDI. Multiple binomial logistic regression defined as independent risk factors for death among CDI patients: advanced age, comorbidities such as chronic obstructive pulmonary disease (p=0.008), chronic kidney disease (p=0.007), or COVID-19 (p=0.036), leukocytes ≥ 16,755/mm^3 (p=0.009) and serum albumin < 2.83 g/dL (p<0.001). Conclusions: The identification of certain negative prognostic factors in patients with CDI requires a careful follow-up of the patients, for an early identification of complications and adaptation of therapeutic management.*

Keywords: *Clostridium difficile; chronic obstructive pulmonary disease; COVID-19; chronic kidney disease; prognosis*

INTRODUCTION

Clostridium difficile infection (CDI) is one of the most common healthcare-associated infections and an important cause of morbidity and mortality worldwide [1]. The latest epidemiological data provided by the European Center for Disease Prevention and Control (ECDC), in 2008, reported an incidence of approximately 4.2 cases of CDI per 10.000 patient-days per hospital, with a range of variation of 0.0-36.3 [2]. According to this report, the incidence of CDI increased dramatically compared to 2005 when an incidence of approximately 2.45 cases of CDI per 10,000 patient-days per hospital was reported, with a range of variation of 0.13-7.1 [3,4]. In the United States of America (USA), in 2012, approximately half a million cases of CDI and 29.000 deaths secondary to this disease were registered [5]. However, because of the implementation of a surveillance and infection prevention program in 10 USA states, the health-care-associated CDI decreased from 92.76 cases per 100,000 inhabitants in 2011, to 66.96 cases per 100,000 inhabitants in 2017 [6]. Regarding the incidence of community-associated CDI in the USA, it increased slightly between 2011 and 2017 (55.3 cases per 100,000 inhabitants in 2011 vs. 70.4 cases per 100,000 inhabitants in 2017) [6]. Another problem is represented by the important recurrence rate of CDI, respectively 20-30% [7]. Beyond the negative impact on the quality of life and life expectancy, the healthcare of these patients involves very high costs. For example, in the USA, 5.4-6.3 billion dollars per year are consumed by these patients [8].

It is also reported a Clostridium difficile carriage rate of 8-10% among hospitalized adults, compared to 3% among healthy adults [9]. Carriers, but asymptomatic patients, represent reservoirs of germs, which can eliminate spores and transmit the infection to other patients [10,11]. A study that followed the prevalence of colonization with Clostridium difficile, at admission, among 250 patients who did not present diarrhea, reported a percentage of 79% of patients colonized with this bacteria [12]. Among them, in 15% of cases, a toxigenic strain was identified, and in 6% of cases a non-toxigenic strain [12]. No differences were identified regarding recent antibiotic use or contact with medical care units between patients colonized with a toxigenic strain vs. uncolonized patients [12]. Also, the concentrations of toxins in stools have been shown to be similar in asymptomatic carriers vs. symptomatic patients [13].

CDI is a public health problem with a major impact on the healthcare system. This can be explained by the significant increase in the incidence after the year 2000, the existence of CDI outbreaks in some hospitals, but also by the appearance of hypervirulent strain NAP1/B1/027 [14,15].

The most common risk factors for CDI are represented by hospitalization, antibiotic use, and advanced age [16-18]. However, there are other risk factors that can modify the evolution and prognosis of these patients, respectively: obesity, severe comorbid illness, inflammatory bowel disease, chemotherapy, enteral feeding, hematopoietic stem cell transplantation, cirrhosis, and gastric acid suppression [19-23]. Regarding the risk of complications, a study that followed 1,380 patients with CDI identified a series of predictive factors for unfavorable evolution: older age, abnormal vital signs (respiratory rate over 20/minute and heart rate over 90 beats per minute), and abnormal blood tests (C-reactive protein ≥ 150 mg/L, albumin < 25 g/L, white blood cell count < 4,000/L or ≥ 20,000/L) [24]. According to data from the specialized literature, all cases' death rate at 30 days in patients with CDI varies between 9% and 38% [25].

Given the burden and the important death rates associated with CDI, we aimed to identify the predictive factors for an unfavorable evolution among patients with CDI. The primary endpoint of the study was the in-hospital mortality rate.

MATERIALS AND METHODS

We conducted a retrospective, observational, non-randomized study in which we evaluated the mortality rate associated with CDI and the risk factors for an unfavorable evolution. We followed 202 patients diagnosed with CDI between January 2020-January 2022 during hospitalization in the Clinical Emergency Hospital of Bucharest, Romania. The study was approved by the Ethics Committee of the Clinical Emergency Hospital of Bucharest (approval no. 10002/ 04.10.2022). The study respected the ethical standards of the Helsinki Declaration of 1975, as revised in 2008(5), as well as the national law. Informed consent was obtained from all the patients included in the study.

The inclusion criteria consisted of the existence of clinical and paraclinical evidence attesting CDI. For the diagnosis, we applied the 2019 European Center for Disease Prevention and Control (ECDC) definition of CDI, respectively: diarrhea or toxic megacolon and a positive test for Clostridium difficile toxins A/B in stool samples or positive polymerase chain reaction (PCR) test for Clostridium difficile; colonoscopic examination that highlighted pseudomembranous colitis; histopathological examination that identified characteristic elements of CDI in a tissue sample obtained by endoscopy from a patient with or without diarrhea [4]. The exclusion criteria were represented by the absence of some clinical-paraclinical data that were followed in the study and the absence of the patient's informed consent. None of the patients initially included in the study were subsequently excluded.

The variables followed in the study are epidemiological data (age, sex), presence of comorbidities (chronic obstructive pulmonary disease, COVID-19, chronic kidney disease, heart failure, atrial fibrillation, diabetes mellitus, arterial hypertension, neoplasms), CDI recurrence, treatment with proton pump inhibitors, a series of biological variables (hemoglobin, number of leukocytes, C-reactive protein, erythrocyte sedimentation rate, fibrinogen, albumin), hospitalization length and death rate.

Statistical analysis

Patient data were obtained from the electronic medical records of the hospital and were centralized in an Excel database. For the statistical analysis, we used the R program, version 4.0.2 [26]. We used a simple univariate binomial logistic regression, the dependent variable being death during hospitalization, and the independent variables' demographic-clinical parameters monitored in the study. Later, the predictors that had statistical significance in the simple model were used in a multiple univariate binomial logistic regression, the model being built with the help of a retrograde selection algorithm of the predictors. We also performed a descriptive statistical analysis of the variables followed in the study. P-values lower than 0.05 were considered statistically significant.

RESULTS

The average age of the patients included in the study was 70.8 years, with a minimum value of 18 years and a maximum value of 95 years. Regarding gender, the proportion was approximately equal, respectively 47% women and 53% men. The average duration of hospitalization was 18.4 days, reaching up to 145 days in more severe cases. During the 2-year follow-up period, only 10 patients (5%) presented a recurrence of Clostridium difficile colitis. Regarding comorbidities, 58.4% of the patients had arterial hypertension (AH), 33.2% heart failure (HF), 29.7% chronic kidney disease (CKD), 27.7% diabetes mellitus, 26.2% atrial fibrillation (AF), 22.8% neoplasms, 22.3% COVID-19 and 3.96% chronic obstructive pulmonary disease (COPD). Among the patients included in the study, 45% were treated with proton pump inhibitors (PPI) (Table 1).

Table 1: Demographic, clinical, and paraclinical analysis of the study group

Variable	Number of patients (N=202)
Age	
Average (SD)	70.8 (15.7)
Median [Min, Max]	73.5 [18.0, 95.0]
Sex	
F	95 (47.0%)
M	107 (53.0%)

Median [Min, Max]	2.90 [1.00, 5.10]
Death	
No	150 (74.3%)
Yes	52 (25.7%)

Legend: COPD = chronic obstructive pulmonary disease; CDI = Clostridium difficile infection; PPI = proton pump inhibitors; CKD = chronic kidney disease; HF = heart failure; AF = atrial fibrillation; DM = diabetes mellitus; AH = arterial hypertension; CRP = C-reactive protein; ESR = erythrocyte sedimentation rate.

Also, a series of biological variables were analyzed, such as the number of leukocytes and the serum values of fibrinogen, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), hemoglobin, and albumin.

The average value of leukocytes was 18,600/mm^3, varying between 2,800/mm^3 and 94,000 mm^3. Also, increased values of inflammatory markers were identified, namely an average value of fibrinogen of 498 mg/dL (107-1,020 mg/dL), an average value of CRP of 118 mg/dL (0.710-371 mg/dL), and an average value of ESR of 43.6 mm/hr (2.00-98.00 mm/hr).

The mean serum hemoglobin was 10.6 g/dL and the mean serum albumin was 2.91 g/dL (Table 1). 52 patients died during follow-up, the death rate being 25.7% (Table 1).

Later, we performed a simple univariate binomial logistic to identify the risk factors for unfavorable prognosis and death (Table 2).

This statistical analysis identified a direct proportional relationship between the mortality rate and the following risk factors: advanced age, association with COVID-19, CKD or COPD, serum hemoglobin < 9.85 g/dL, leukocyte count ≥ 16,755/mm^3, CRP ≥ 104.02 mg/dL, serum albumin < 2.83 g/dL. Increasing age by 1 year was associated with a 2% increase in the death rate (p=0.048, 95% CI 1.02 (1.00-1.05)).

Legend: COPD = chronic obstructive pulmonary disease; CDI = Clostridium difficile infection; PPI = proton pump inhibitors; CKD = chronic kidney disease; HF = heart failure; AF = atrial fibrillation; DM = diabetes mellitus; AH = arterial hypertension; CRP = C-reactive protein; ESR = erythrocyte sedimentation rate.

The predictors that had statistical significance in the simple model were later used in a multiple univariate binomial logistic regression, the model being built with the help of a retrograde selection algorithm of the predictors (Table 3). This statistical analysis identified COVID-19 as an independent risk factor, with an approximately 3-fold increase in the risk of death (95% CI 0.39 (0.16 – 0.94); p=0.036). Other factors associated with an independent increase in the risk of death, among the patients included in the study, were: the presence of CKD, with a 3-fold increase in the risk of death (95% CI 0.33 (0.15 – 0.73); P=0.007), the presence of COPD, with a 20-fold increase in the risk of death (95% CI 0.05 (0.00 – 0.33); p=0.008), the number of leukocytes ≥ 16,755/mm³, which led to an approximately 3-fold increase in the risk of death (95% CI 2.82 (1.31 – 6.22); p=0.009) and the value of serum albumin < 2.83 g/dL, which led to a 4-fold increase in the risk of death (95% CI 0.23 (0.09 – 0.50); p<0.001) (Table 3).

DISCUSSION AND CONCLUSIONS

Clostridium difficile colitis is one of the most common nosocomial infections in developed countries, for which higher morbidity and mortality rates were reported after 2000 [27]. In the USA, approximately half a million patients are diagnosed with CDI annually [28]. This phenomenon is partially explained by the spread of a more virulent strain, ribotype (RT) 027, after the year 2000, in the context of the increase in life expectancy and population aging [27,29]. However, the global burden associated with CDI decreased by 24% between 2011 and 2017 in the USA, due to the reduction of healthcare-associated infections [6]. The rates of reinfection with Clostridium difficile and mortality associated with this condition did not change significantly during this period [6, 30]. An explanation for the reduction of the global burden of CDI was represented by the natural decrease of RT 027 or as a result of the large-scale reduction in the use of fluoroquinolones [30-32]. Also, other strains that can be associated with a possible unfavorable evolution, such as RT 244 or 078, were rarely identified in the USA [33,34]. In 2016, ECDC reported 7711 cases of CDI in 20 member states of the European Union, 74.6% being associated with nursing [35]. The most frequent RT were 027 (22.9%), 001 (7.5%), 014 (6.7%), 078 (5.1%), 002 (4.2%), and 020 (4.2%) [35]. The all-cause mortality rate among these patients was 20.7% [35]. In Romania, the average prevalence of CDI is 5.2 cases per 10,000 patient days, increasing to approximately 25 cases per 10,000 patient days in the departments of gastroenterology or infectious diseases [36]. The dominant RT in Romania is 027. A study that followed 393 patients with CDI identified RT 027 in 82.6% of cases (95% CI: 73.6%-89%) [36]. Other identified RT were: 002, 018, 087, 014, 001, 011, 012, 017, 020, and 106 [36].

In our study, the average age of patients diagnosed with CDI was 70.8 years, and the death rate from all causes was 25.7. These results correspond to those reported in the literature. Redelings et al. reported an increase in the mortality rate associated with CDI in the USA from 5.7 deaths per 1 million individuals in 1999 to 23.7 deaths per 1 million individuals in 2004 [37]. The same authors reported an average age of patients whose death was associated with CDI of 82 years [37]. Another study that followed 66 patients with CDI, aged over 65 years, reported the following mortality rates: 11.5% at 7 days, 26.2% at 30 days, 38.1% at 90 days, and 41.4% at 180 days. Mitchell et al. highlighted a variability of all-cause mortality at 30 days in patients who had associated CDI between 9% and 38% and of in-hospital mortality between 8% and 37.2% [38]. The directly proportional relationship between advanced age and poor prognosis among patients diagnosed with CDI was also highlighted by a multicenter study that followed patients from hospitals in Quebec [39]. These authors highlighted the increase in the 1-year mortality rate among patients with CDI from 4.7% in the 18-64 years age group to 21.1% in the 65-74 years age group [39]. In our study, increasing age by one year was associated with increasing the risk of death by 2%.

Regarding the average length of hospitalization of the patients included in our study, it varied between one day and 145 days, with an average value of 18.4 days. This result corresponds to data from the literature [40-42]. Thus, Hebbinckuys et al. reported an average length of hospitalization of 18.5 days for patients with CDI, which can vary between 6 and 132 days [40]. Another study compared two groups of patients hospitalized for various ailments: the first group consisted of 38 patients who had associated CDI and the second group consisted of 76 patients who did not have associated CDI [41]. In the first batch, the average duration of hospitalization was significantly higher compared to the second batch (31.5 days vs. 5.5 days) [41]. The conclusion of this study was the increase of the average duration of hospitalization by approximately 4 days by the association of CDI ($p<0.001$) [41]. During the study, only 5% of the patients presented a recurrence of infection with Clostridium difficile. According to ECDC, the recurrence rate of CDI in Europe is approximately 7.9% [35]. Other studies reported higher rates of recurrence of CDI, respectively 15-30% [43,44]. The factors associated with the risk of CDI recurrence are advanced age, infection with hypervirulent strains, history of CDI and their severity, longer duration of hospitalization, use of antibiotics for non-CDI after establishing the diagnosis of CDI, use of gastric acid suppression drugs or renal failure [44,46,47]. An explanation for the lower recurrence rate of CDI in the population included in our study can be represented by the absence of an infectious disease department in the hospital where the study was carried out. Under these conditions, there is the probability that in case of relapse, some of the patients would have presented to other hospitals.

Among the comorbidities of patients included in our study, we list in order of their frequency: arterial hypertension, heart failure, CKD, diabetes mellitus, atrial fibrillation, neoplasms, COVID-19, and COPD. This wide range of comorbidities can be explained by the advanced age of the patients, the average age being approximately 71 years. Feuerstadt et al. identified among the most frequent comorbidities in CDI patients: HF, COPD, diabetes without complications, peripheral vascular disease, and renal disease ($p < 0.01$) [48]. Our study validates these results, adding to the comorbidities also COVID-19, being performed during the pandemic. According to data from the literature, the association of other diseases in patients with CDI leads to an increase in the disease burden, by increasing the risk of polypharmacy, compromising the immune status, and increasing the duration of hospitalization [49]. Almost half of the patients had treatment with proton pump inhibitors (PPI). A recent meta-analysis that included eight studies from the USA, Canada, Europe, and Asia highlighted a statistically significant association between PPI use and the risk of developing CDI [50]. Inghammar et al. also highlighted the fact that the risk of developing CDI remains high even one year after stopping PPI treatment [51]. Another meta-analysis that included 356,683 patients concluded that the use of PPIs leads to an increase in the risk of developing CDI in both groups, inpatients, and outpatients [52].

From a paraclinical point of view, the statistical analysis identified leukocytosis, inflammatory syndrome, mild anemia, and hypoalbuminemia among the patients included in our study. A prospective study that followed 60 patients with unexplained leukocytosis identified the presence of Clostridium difficile toxins in fecal specimens in 58% of them [53]. The data currently available suggest the need to perform paraclinical tests in order to identify CDI in hospitalized patients who develop leukocytosis [53,54]. A series of studies demonstrated the correlation between elevated CRP values, anemia, hypoalbuminemia, and the unfavorable prognosis of patients with CDI [55-60]. Ahmed et al. have highlighted the fact that the decrease in serum albumin values and the increase in the ATLAS score (which includes age, albumin and creatinine values, the number of leukocytes, and treatment with antibiotics during CDI therapy) among patients with Clostridium difficile colitis reflect the worsening of the disease [58].

The main objective of our study was to identify the predictive factors for unfavorable evolution and death among patients with CDI. The simple univariate binomial logistic regression identified the following risk factors for death: advanced age, comorbidities such as COVID-19, CKD, and COPD, but also the values of some paraclinical markers, such as serum hemoglobin < 9.85 g/dL, leukocyte count ≥ 16,755/mm^3, CRP ≥ 104.02 mg/dL and serum albumin < 2.83 g/dL. Later, the multiple binomial logistic regression analysis defined advanced age, the association of COPD, CKD, or COVID-19, the number of leukocytes ≥ 16,755/mm^3, and the serum albumin value < 2.83 g/dL as independent risk factors for death. A study carried out in Taiwan, which followed 401 patients with CDI, highlighted a 30-day mortality rate of 23.4%; among the predictive factors for death were age > 65 years, serum albumin value < 2.5 g/dL, and increased creatinine by 1.5 times [61]. De Miguel-Diez et al. highlighted a doubling of the incidence of CDI and an increase in mortality among patients with COPD compared to the general population [62].

Regarding the evolution of patients who associate CDI and COVID-19, our study validates other data from the literature [63,64]. Thus, a study that followed 2065 patients with COVID-19, of whom 40 had CDI, highlighted a more severe evolution among patients who combined both diseases, with 45% of them developing complications, and 22.5% dying in hospital [63]. The extensive use of antibiotics during the COVID-19 pandemic increased the risk of CDI development [63]. According to other studies, CKD increases both the prevalence and severity of Clostridium difficile colitis [65-67]. This phenomenon can be explained by the frequent hospitalizations of patients with CKD, but also by other factors such as the frequent use of antibiotics or PPIs, alteration of the immune system, or intestinal dysmotility [65]. Keddis et al. highlighted a higher prevalence of CDI among CKD patients compared to the general population (1.49% vs 0.70%) [66]. The same authors identified in the group of patients who had both CKD and CDI, compared to patients with CKD without CDI, longer average hospital stays (7 days vs. 4 days), higher rates of colectomy (0.67% vs. 0.28%) and higher death rates (6.62% vs. 3.99%) [66].

The peculiarity of our study consists of the follow-up of patients with CDI during the COVID-19 pandemic. The mortality rate did not show significant differences compared to the one recorded before the pandemic, but the CDI recurrence rate was slightly lower compared to that reported by the literature. This result can be explained by the patients' fear of infectious diseases and their presentation in case of relapse in infectious disease clinics. The main limitation of our study is the lack of differentiation between community cases of CDI and those associated with medical assistance.

In conclusion, CDI is a public health problem due to both high incidence rates and high mortality rates, especially among elderly patients and those with important comorbidities. To improve the therapeutic management and prognosis of these patients, more effective systems for risk identification are needed. In this regard, our study sought to identify a series of predictive factors of death among patients with CDI. Patients who present the clinical and paraclinical profiles described above as being at high risk of unfavorable evolution and death require more careful monitoring for the early identification of possible complications and optimal treatment. Also, these risk factors can contribute to the correct selection between ambulatory treatment, hospitalization, or the need for intensive therapy measures.

Abstract: *Background: The prevalence of smoking among students is a growing concern, particularly among medical students. Being associated with stress, competitiveness, and various social influences, smoking can have detrimental effects on self-esteem and self-efficacy and may create a vicious cycle that may contribute to student's well-being and academic performance outcomes. We aimed to investigate the relationship between self-esteem, self-efficacy, and smoking habits among medical students and their sociodemographic correlates. Methods: A cross-sectional study on 456 medical students was conducted via an online survey using structured questionnaires on socio-demographic characteristics, smoking habits, nicotine dependence, self-esteem, and self-efficacy. Results: The prevalence of smoking was 31.1% The scores of self-esteem and self-efficacy were positively correlated with smoking habits (W1=0.957, W2=0.975, P<0.05). Students presented rather low smoking addiction with male students having slightly higher scores than female students on self-esteem and self-efficacy, military students had higher self-esteem scores than civilians with physical activity having a positive correlation with non-smoking behavior. Conclusion: According to our results, self-esteem and self-efficacy were slightly positively correlated with smoking habits. Furthermore, there was no statistically significant association between other social factors and smoking. Our results may develop a theoretical basis for medical students' psychological variables studying for further implementation of university educational programs and preventive interventions empowering students towards an overall better quality of life, addressing, among others, smoking behaviors.*

Keywords: *prevalence, smoking, medical students, self-esteem, self-efficacy*

INTRODUCTION

Stress is a common experience for most medical students due to the rigorous demands of their training with medical education being challenging and students often facing heavy workloads and competition pressure situations. Having to absorb and retain a large volume of complex information, time pressure, and expecting to academically perform at a high level can create a significant amount of mental distress. Major years students can have even more challenging and stressful experiences as they are often exposed to the presentation of critically ill patients and life-threatening emergencies with supplementary emotional input. With less time for socializing, hobbies, or self-care and other socio-economic difficulties, medical students can develop various stages of burnout and use unhealthy coping mechanisms, especially after the COVID-19 lockdown when coping mechanisms deteriorated with smoking and drinking, among others, important factors of the stress perceived [1,2,3].

Smoking is one way, among others, that people usually cope with stress with nicotine providing a temporary sense of relaxation. However, smoking has been linked to a variety of negative health outcomes, including lung cancer, heart disease, and stroke, comprising 16% of non-communicable diseases, in Romania [4,5]. In addition, smoking can increase stress levels over the long term by disrupting sleep, reducing exercise tolerance, and impairing lung function [6,7].

There have been several studies that have looked at the link between smoking and stress in medical school. One study found that medical students who reported high levels of stress were more likely to smoke, with around 30% of students reporting smoking, and that smoking was more common among male students [8]. In Europe, the prevalence of smoking among medical students varies from 28.02% in Germany to 31.3% in Italy, which is higher than in the general population [9] and compared to students from other faculties [10]. Stress and symptoms of anxiety and depression increase in the first two years of medical studies but decrease towards their end [11]. In doctors, stress and burnout are rather typical. Both issues could start during medical school and continue during residency and then across a lifetime. Medical schools need to be informed about the persistent and important effects of stress and burnout among their students.

The effects of smoking on various psychological variables have been a topic of interest in recent years with studies investigating the relationship between smoking and mental health, including self-esteem and self-efficacy. Smoking was negatively associated with self-esteem and self-efficacy in medical students. This negative relationship is believed to be due to the harmful effects of smoking on both physical and mental health. Smoking may affect one's social and emotional well-being, leading to feelings of isolation and reduced self-worth. Smokers may also experience academic problems, which can further reduce their self-esteem and self-efficacy [12].

Unfortunately, smoking is not the only factor that comes along with stress. A vicious cycle is formed between smoking, low self-esteem, and low self-efficacy. A study published found that these factors were significant predictors of academic performance among medical students. Higher levels of stress were associated with lower academic performance, while higher levels of self-esteem were associated with better academic performance. The study also found that there was a significant negative correlation between stress and self-esteem [13]. Medical students who smoked had lower self-esteem than non-smoking students. Similarly, a study found that smoking was associated with lower self-esteem in medical students. The concerning part is that self-esteem and self-efficacy were negatively associated with smoking and that higher levels of self-efficacy were associated with a lower likelihood of smoking. [14].

The importance of self-esteem and self-efficacy was highlighted by their influence as mediating the relationship between motor proficiency and internalizing problems along with social support. This represents an important aspect of the concept of the environmental stress hypothesis which may also relate to unhealthy coping mechanisms such as smoking [15]. In recent years, there are no studies including all three variables as included in our research. This may represent a more complete understanding of how these psychological variables impact smoking behavior. Even if there are some studies regarding military medical students [16] we found no approaches concerning this type of students in aspects of self-esteem or self-efficacy. The social component is not discussed enough as loneliness and social circle may influence smoking behavior [17].

Thus, this study aimed to examine the relationship between smoking prevalence, self-esteem, and self-efficacy in medical students. Additionally, this study`s secondary aims were to compare these factors based on socio-demographic characteristics and investigate their potential correlation. Our hypothesis was based on correlations between variables but no presumptions as to whether they were negative or positive were made in advance. Also, there is likely that coping mechanisms may represent an additional factor for smoking behavior prevalence. Moreover, military students are expected to have lower self-esteem and self-efficacy scores as their military service goes along with their medical training with stress levels being considered higher.

MATERIALS AND METHODS

Study design and participants

The design of the study was cross-sectional, comprising a survey of 22 questions and three standardized psychometric instruments. The cross-sectional design was successfully used in previous literature on addictive behaviors [18,19], including in Romania [20,21].

456 medical students from the first three years of study (33.1% men, 65.7% women, 1,09% other; mean age = 20.8, SD = 2.24) agreed to participate in the study and answered the psychometric tests.

The inclusion criteria were as follows: (1) students currently studying at the university (2) obtained informed consent and willingness to participate in the study.

Context and Procedure

The data were gathered in April–May 2023 through the administration of an online survey containing the study instruments. Firstly, we informed the participants of the study’s aims. Participation was anonymous, and students’ responses did not affect the teacher’s evaluation of the student’s academic performance.

The study procedure was run via a SurveyMonkey® interface (One Curiosity Way, San Mateo, CA, USA). Online testing in university settings is reported to ensure the speed and representativeness of the collected data [22,23].

Methods in the study were designed according to the World Medical Association`s Declaration of Helsinki. The study protocol was approved by the UMFCD Ethics Review Board (no. 14873/2023). All responses were processed anonymously and a numerical code was assigned to each respondent. The data were accessible exclusively to study researchers (LM, CGI, MS). The interpretation of the questionnaires was performed independently by two researchers (MS, CGI). Results were included in a JASP version 0.10.2 statistical software (Department of Psychological Methods the University of Amsterdam, Amsterdam, The Netherlands, https://jasp-stats.org/) database.

Questionnaires

Three standardized psychometric instruments were used to measure their smoking addiction, self-esteem, and self-efficacy scales.

(1) The Fagerstrom Test for Nicotine Dependence (FTND) is a questionnaire used to measure the degree of nicotine dependence in cigarette smokers. The answers to the 6 questions are used to calculate a total score, with higher scores indicating greater nicotine dependence. Across literature studies, the scale has been shown to have good internal consistency, good validity, and a fairly stable factorial structure [24,25]. Even if sometimes it has a low consistency (0,4-0,6), it is rather acceptable in literature [26].

(2)The Rosenberg Self-Esteem Scale (RSES) is a commonly used scale for measuring self-esteem. It consists of ten statements, to which the respondent rates their level of agreement on a 4-point scale ranging from strongly agree to strongly disagree. The scale measures both positive and negative feelings about oneself, with higher scores indicating higher levels of self-esteem. Responses are scored from 0 to 3, with the total score ranging from 0 to 30. A higher score indicates higher self-esteem [27,28].

(3)The Schwarzer and Mathias self-efficacy scale, also known as the General Self-Efficacy Scale (GSE), is a psychometric tool designed to measure an individual's self-belief in their ability to handle difficult situations and achieve their goals. It consists of ten statements that participants rate on a four-point scale, with higher scores indicating greater self-efficacy. Scores are then calculated and interpreted to provide an overall measure of an individual's self-efficacy. [29,30].

In addition to these three psychometric tests, the participants provided information about their age, place of origin, current academic year, type of training-medical or civilian, current residence, specialty, and coping mechanisms.

Data analysis

We first described the demographics of our participants. The internal consistency of the smoking addiction, self-esteem, and self-efficacy scales was assessed using Cronbach's alpha coefficient and all instruments had coefficients above 0.7, which is considered to be the minimum acceptable value for proper reliability [31].

We made descriptive statistics using all the data depending on the smoker/non-smoker status. Afterward, we performed T-tests to compare various groups on the three main variables studied: smoking addiction, self-esteem, and self-efficacy. Furthermore, we used Chi-Squared tests to quantify differences in smoking/non-smoking depending on the place of living and gender. Other T-tests were used to compare the three scales depending on situations when smoking, coping mechanisms, and type of cigarettes smoked.

Data management and descriptive analyses were performed using JASP statistical software, version 0.17.2 statistical software [32].

Ethical Considerations

- Participants were appropriately informed about the nature of the research.
- Informed consent was taken from the participants.
- Anonymity of participants and confidentiality of the information was maintained.
- Participants were given the right to withdraw from research at any time.
- The responses were accurately represented

RESULTS

Sociodemographic data and smoking correlates

The response rate was 10.08% (456 out of 4521 medical students invited). Data was collected from 456 students who agreed to participate in the study (151 men, 300 women, 5 not specified gender; mean age = 20.88, SD = 2.24). A total of 86.8% of the participants were Romanian module students with 14.2% reported being Military Medicine students and only 27.4 % reporting living in a student campus (complete detailed results in Table S1. Supplementary Materials). Table 1 summarizes the descriptive indicators of the socio-demographic data.

The Fagerstrom nicotine dependence test showed a low mean level of nicotine addiction among medical students (m = 1.45, SD =1.406) [33]. The data reveal interesting patterns in smoking behavior across different sociodemographic categories.

As expected, the majority of both smokers and non-smokers are from Civil Medicine (being the majority), but the proportion of smokers in Military Medicine is noticeably higher than that met in Civil Medicine students. This could suggest a potential association between the stressors or lifestyle factors specific to Military Medicine and smoking behavior. In terms of residence, while the majority of both groups reside in personal properties, there is a slightly higher proportion of smokers residing on campus, probably due to frequent casual socialization. Details can be seen in Table 2.

Table 1: Sociodemographic characteristics of the sample

Variable	Condition	Participants (n)	Percent (%)
Gender	Female	300	65.79
	Male	151	33.11
	Other	5	1.10
Study module	Romanian module	396	86.84
	English module	56	12.28
	Missing	4	0.88
Specialty	Civil Medicine	391	85.75

	Campus	40	28.17
	Personal propriety	102	71.83
	Total	**142**	100.00

Patterns in smoking: risk situations and alternative coping

Next, we will deal with two opposing factors relevant to smoking: contexts that increase the risk of smoking behaviors and coping strategies that may lower its frequency or diminish its impact. Concerning the types of contexts that trigger smoking the results are presented in Table 3. The data reveal that the majority of smokers reported experiencing academic stress (78.17%) and social smoking (90.14%) as extremely common contexts for smoking. In contrast, emotional conflicts were reported by a smaller, yet still substantial, proportion of participants (66.90%).

Table 3: Types of situations for smoking

Situations	Present	Participants (n)	Percent (%)
Academic stress	Yes	111	78.17
	No	31	21.83
	Total	142	
Social smoking	Yes	128	90.14
	No	14	9.86
	Total	142	
Emotional conflicts	Yes	95	66.90
	No	47	33.10
	Total	142	

The alternative coping to smoking can be seen in Table 4. Not surprisingly, the mean score for smoking within the group engaged in physical activities is lower (1.260) compared to the group not engaged in physical activities, with a mean score of 1.774.

Table 4: Coping Strategies for Smoking

Strategy	Present	Participants (n)	Percent (%)
Mindfulness	Yes	43	30.28
	No	99	69.72
	Total	142	
Relaxation	Yes	89	62.68
	No	53	37.32
	Total	142	
Physical activity	Yes	66	46.48
	No	76	53.52
	Total	142	

Other methods for coping with stress reported verbatim by participants are music therapy, reading, and some negative methods such as alcohol, marijuana, and binge eating. There is also another series of apparently linked factors that are not actually related to smoking behavior. We found no significant correlation of Fagerstrom nicotine dependence results with gender, language module, military vs civilian module, area, living place, previous psychotropic treatment, previous psychotherapy, and starting before entering university (All the statistical analyses results are attached in Supplementary Materials).

There is no significant difference in smoking addiction scores between students who practice mindfulness and those who do not ($p>0.05$). Based on these p-values, there is no convincing evidence to suggest a significant difference in the measured variables between the relaxation and no-relaxation groups.

Self-Esteem, Self-Efficacy, and their socio-demographic correlates

The Self-Esteem assessment showed practically no difference between smokers/non-smokers (30.09 vs 30.98). The prototypical participant with high self-esteem is male, a Romanian module student, a Military Medicine student, from urban areas, living on campus, with no previous psychotropic treatment and no psychotherapy.

Overall, the differences in mean scores between individuals engaged in physical activities and those who are not are relatively small across the variables.

Differences in Self-Esteem and Self-Efficacy between Smokers and Non-Smokers

Significant differences were found between non-smokers and smokers in terms of self-efficacy and self-esteem. Smokers reported higher levels of self-efficacy ($p = .001$, $rpb = -0.198$) and self-esteem ($p = .044$, $rpb = -0.123$) compared to non-smokers. The effect sizes for the significant results were small to medium, suggesting the practical significance of the findings (Table 5).

The evaluation of the effort capacity from 0 initial value has reached 10 minutes without effort disorders so that later on the final evaluation on the best day of the patient will be 15 minutes without effort disorders. We mention that every day the patient's dynamics undergo changes from one hour to the next and the time of day matters a lot.

DISCUSSION

Smoking prevalence

Only one-third of the students responding to our survey were smokers, but rather low addiction scores were reported as confirmed by the Global Adult Tobacco Survey (GATS) 2018 study in a sample of the Romanian general population, remaining unchanged since 2011 [34]. There were no gender differences regarding smoking addiction with most of the smokers living in their own houses. Also, academic stressful situations and intense emotional conflicts were reported as the most frequent situations when students smoke as another study previously reported [35]. This may represent a norm for young adults as addictive behaviors were previously reported as adopted in various stressful situations, especially work and family-related ones [36].

Table 5: Comparison of Self-Efficacy, Rosenberg Self-Esteem, and Fagerstrom Test for Nicotine Dependence Scores Between Non-Smokers and Smokers

Dependent Variable	Non-Smokers			Smokers			U	p	r_{pb}
	N	M	SD	N	M	SD			
Self-Efficacy	271	30.705	4.155	132	32.265	4.608	14350.5	.001	-0.198
Self-Esteem	265	30.098	5.1	134	30.985	5.61	15571.5	.044	-0.123
Nicotine Dependence		-	-	81	1.457	1.406	-	-	-

*Note. M and SD represent the mean and standard deviation, respectively. U represents the Mann-Whitney U test statistic. p represents the p-value for the Mann-Whitney U test. rpb represents the rank biserial correlation, which is the effect size for the Mann-Whitney U test. All p-values are two-tailed. Effect sizes were calculated using the formula rpb = 1 - (2U / (n1 * n2)), where n1 and n2 are the sample sizes for the two groups*

Otherwise, our results may present an optimistic outcome concerning the relatively low degree of addiction even in those starting smoking before entering university and taking into consideration the growth in consuming heat-ed-tobacco products (HTP) as Romania is the second Euro-pean country reporting the use of HTPs [37,38]. This perspective is confirmed by studies including Romania as being the 9th EU member state on smoking prevalence and 10th on pack-year prevalence but persisting on a descendent trend in contrast to other Eastern European countries like Bulgaria or Greece [39,40].

Concerning coping mechanisms, only physical activity had a significant correlation to low smoking addiction scores. Physical activity, among others, was highlighted as an important predictor of health outcomes across life stages, including smoking [41,42].

Self-esteem, self-efficacy, and smoking prevalence

The present study aimed to investigate the relationship between smoking addiction with self-reported self-esteem and self-efficacy among medical students. The results showed that correlations between smoking addiction and self-esteem/ self-efficacy were positive, indicating that higher levels of smoking addiction were associated with higher levels of self-esteem and self-efficacy. However, it is important to note that the correlations were relatively weak and not statistically significant. It is important to retain that only one-third of the students declared smoking with 78.8% starting before entering university. The mean scores on the smoking scale were showing rather low addiction. This may represent a point of interest in discussing why the majority of the students did not develop a higher addiction since they began smoking a few years now. Based on the results of this study and the literature as well, it seems it is necessary to conduct more studies in this area, especially longitudinal and interventional studies to practically determine the effect of self-esteem and self-efficacy improvement programs on smoking prevention or cessation.

Most of the studies rank medical students among the students with low self-esteem and self-efficacy [43,44] this leads to various mental health issues like depression, anxiety, and burnout [45]. Also, most of the studies rank them lower than non-medical students regarding smoking [46,47,48]. Few studies tried to correlate the variables of self-esteem and self-efficacy with smoking addiction levels.

Our study found results that may explain the protective role high self-esteem and self-efficacy hay have in stopping students not to develop higher levels of addiction as the years go by. Also, the finding might be a result of cumulated factors including social interactions, breaks between learning sessions, but also other coping mechanisms that interfere with these results (mindfulness, relaxation, physical therapy, etc.)

With most of the studies focused on smoking cessation and self-esteem and self-efficacy [49-52] having predictor roles for successful abstinence and not advancing in higher stages of addiction, our study stays in line with those findings. Also, happiness was associated with lower scores of smoking in young adults [53] confirming our relatively low addiction scores in our research.

While few studies correlate high self-esteem and self-efficacy with habits like smoking [54] others show negative correlations, especially among young adults progressing in smoking [55-58] with negative social capital being also linked with smoking behavior [59]. In contrast, a study shows that self-esteem may not represent a predictor for smoking [60]. This may be considered important in the light of social, economic, and cultural characteristics of the Romanian population.

Gender differences

Gender differences were observed in the study, with males tending to have slightly higher self-efficacy and self-esteem scores compared to females which is supported by previous research [61]. Also, gender can influence social expectations and perceptions, which may further affect self-esteem and self-efficacy [62]. There was no significant difference in smoking addiction scores between genders. This suggests that gender alone may not be a significant factor influencing smoking addiction.

Other social correlates

The study found that individuals in the military group had higher self-esteem scores compared to the civilian group. This suggests that the context of military service may positively influence self-esteem.

Studies have shown that military medical students may vary in matters of well-being, depression, burnout, or the tendency to leave medical school while trying to adopt more coping strategies [63,64]. Military medical students are a unique population to study in relation to smoking, self-esteem, and self-efficacy, knowing that military service members and veterans have been found to have higher rates of smoking than the general population. Military medical students may face additional stressors related to their military obligations, such as deployments, training exercises, and other demands of military service. These stressors may impact their self-esteem and self-efficacy and may also influence their smoking behavior.

Students living on campus had higher self-esteem scores compared to those who lived alone. The social environment and support provided in the campus setting may contribute to higher self-esteem as highlighted before [65].

Individuals engaged in physical activities had slightly higher self-efficacy scores and lower smoking addiction scores. Physical activity and exercise can positively impact self-esteem and self-efficacy through improved physical well-being and feelings of accomplishment. Students engaged in physical activities had lower smoking addiction scores compared to those who were not engaged in physical activities. This suggests that being physically active may have a positive influence on reducing smoking addiction and improving overall quality of life as previous research showed [66,45,67].

CONCLUSIONS

In our study, self-esteem and self-efficacy were rather high among smokers and non-smokers as well. Our study suggests that there may be other psychological variables worth taking into consideration concerning smoking habits, like personality, cultural background, social attitudes, and mental individual variables. There is a need to investigate the cultural and social aspects of smoking in Eastern European countries like Romania where smoking policy and education still have a lot of space for improvement.

Self-esteem and self-efficacy were reported as high in most of our participants. Medical students are required to have higher intellectual effort and engagement than most of the superior education systems thus there is a need for confidence and self-enhancement to perform academically at the expected standards.

Smoking may not represent at the moment, in their first three years of study, a matter of concern regarding physical or mental aspects but the lifetime perspective needs to be addressed.

So, medical students need to be aware of the negative effects of smoking on their mental and physical health, as well as their academic performance. Quitting smoking and adopting healthy lifestyle habits can lead to improvements in self-esteem and self-efficacy, which can ultimately lead to better academic performance and overall well-being. Further research is needed to explore the specific mechanisms underlying the relationship between smoking and self-esteem/self-efficacy in medical students. It becomes crucial to address this issue through preventive interventions. By promoting smoking cessation and the adoption of healthy lifestyle habits, it is possible to break the cycle and potentially improve self-esteem and self-efficacy among students. These improvements, in turn, can lead to positive outcomes in academic performance and overall well-being.

Smoking is a major public health concern and understanding the factors that contribute to smoking behavior can help inform interventions and policies aimed at reducing smoking prevalence considering Romania already signed the WHO Framework Convention on Tobacco Control (FCTC), when a national campaign was launched as “the First Generation without Tobacco” endorses the WHO ‘tobacco end game’ by 2035 [68,69,70].

Understanding the relationship between smoking, self-esteem, and self-efficacy can help identify potential targets for intervention and provide insights into the psychological processes underlying smoking behavior. Medical students are at a critical point in their education and career development; addressing smoking behavior among medical students can have important implications for their future patients, as well as for the broader medical profession.

Limitations

This study has several limitations. The sample size was rather small, and the participation in the survey was based on self-selection. The sample was asymmetric in terms of gender and origin while the design of the study was cross-sectional, not allowing the assessment of the study variables in their long-term perspective. Also, the sample size only included the first three years of medical students mainly from Bucharest and Muntenia southern region of Romania. This may reduce the generalizability of the findings, taking into consideration cultural, social, and attitude aspects toward smoking.

Future Research

Next, studies on this subject could be run longitudinally and include other potentially relevant variables (e.g., pertaining to personality or other psychopathological variables). Moreover, a distinct line of development could be represented by the creative use of the qualitative methodology among medical students.

The in-depth evaluation of personality traits, mental and physical well-being, and social circle employing, for example, self-enhancement or counseling groups, could not only supplement the data, but also offer a valuable opportunity for students to reflect on the complex etiology of smoking and other addictive behaviors, and assess them in relation to their life and academic goals.

Author Contributions

M.L. and M.S. contributed to the design of the work. M.S. conducted the data collection. M.S. and C.G.I. conducted the data analyses. M.S. contributed to the interpretation of the results. C.G.I., S.P., M.S., and M.L. contributed to drafting the manuscript. M.L. and S.P. supervised the development of the work and helped with manuscript evaluation. M.S., S.P., and C.G.I. helped to evaluate and edit the manuscript.

Funding

This research received no external funding.

Institutional Review Board Statement

The study was conducted according to the guidelines of the Declaration of Helsinki and approved by the Ethics Committee of the „Carol Davila" University of Medicine and Pharmacy — Bucharest, Romania (no. 7872/2021).

Informed Consent Statement

Written informed consent has been obtained from the participants to publish this paper" if applicable.

Data Availability Statement

The data presented in this study are available on reasonable request from the corresponding author.

Acknowledgments

The authors would like to warmly thank all the students that participated in the study.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under ‘ETHICAL CONSIDERATIONS (Further Information)’ later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section ‘Parts of the manuscript’, including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

Abstract: *Synovial proliferation is a common intraoperative finding during total knee arthroplasty (TKA) and many studies have proposed synovectomy for the reduction of postoperative pain. We included 180 patients that were split into two groups, one which received a total synovectomy (TS) and the other with partial synovectomy (PS). We measured the amount of intra- and post-operative bleeding as well as perceived pain (using the Visual Analogue Scale) and knee function (using the Knee Society Knee Score) at 4 and 12 weeks. The blood loss during the surgical procedure was 367.77 ± 115.71 mL for TS, while the other group recorded 295.55 ± 106.17 mL ($p < 0.05$). Regarding postoperative bleeding, the TS group aspirated 533.77 ± 281.65 mL, which was significantly higher than the PS group (404.44 ± 211.55 mL, $p < 0.05$). No significant differences were recorded between the TS and PS groups regarding pain and knee function at 12 weeks. Total synovectomy demonstrated significantly higher blood loss and lower postoperative hemoglobin levels, even though knee function and pain level did not show improvements. We consider that the decision of performing synovectomy should rely on the clinical indication and, if conditions allow for it, a limited resection should be attempted***.**

Keywords: *synovectomy; total knee arthroplasty; osteoarthritis; therapeutic method; pathophysiology; surgical technique; joint replacement*

INTRODUCTION

Osteoarthritis is common in the elderly population and is the most frequent condition affecting the synovial joints, especially the knee. Restricted range of motion, discomfort, and local pain are the main symptoms deriving from progressive cartilage deterioration of the articular surface of the knee joint [1,2]. A decisive role in cartilage degrading is played by chronic inflammation of the synovial membrane, known as synovitis [3,4]. Furthermore, residual synovial tissue can be associated with postoperative impingement and decreased range of motion [4,5].

Total knee arthroplasty (TKA) is regarded as a radical effective treatment for patients with end-stage knee osteoarthritis [6,7]. This intervention is typically reserved for individuals who experience severe, persistent pain and mobility issues that cannot be adequately addressed through more conservative interventions such as anti-inflammatory medications or physical therapy. In advanced osteoarthritis, patients experience continuous pain that is unresponsive to typical anti-inflammatory medications, and radiographic imaging shows a narrowing of the joint space and the formation of bony growths known as osteophytes [8].

During total knee arthroplasty, surgeons often identify synovial proliferation in patients with osteoarthritis or other inflammatory conditions [3,9-11]. This proliferation of the synovial membrane can contribute to inflammation and cartilage degradation, leading to decreased joint function and increased pain. Surgical synovectomy involves excising the proliferated synovial membrane and was shown to improve joint function and reduce pain in patients with osteoarthritis [3,9,10]. However, while this procedure can be effective in reducing pain and inflammation, it also carries risks and potential complications that need to be carefully evaluated on a case-by-case basis.

Usually, the surgeon opts for the type of synovectomy depending on intraoperative assessment or personal preferences. Therefore, some surgeons perform total synovectomy as a mandatory step in the surgical technique of total knee arthroplasty, while other surgeons rather avoid performing total synovectomy because they consider it a substantial factor in postoperative bleeding [12-14]. Some researchers suggested that total synovectomy influences postoperative blood loss and operative time without being beneficial in terms of postoperative pain and knee function [12,15].

Decreasing postoperative discomfort and pain is essential to achieve a fast and efficient recovery and to improve the patient's living quality [16,17]. The primary objective of this study is to assess the influence of synovectomy performed during total knee arthroplasty for knee osteoarthritis on blood loss, postoperative pain, knee range of motion, and function.

MATERIALS AND METHODS

1. Study design

We conducted a prospective single-center randomized controlled trial between January 2022 and June 2022. A total of 180 patients were included and split into two even groups, one which received a total synovectomy (TS) and another with partial synovectomy during total knee replacement (PS). The randomization was performed by an independent doctor using sealed envelopes. The envelopes were stored in a box. The envelopes were drawn before surgery and contained instructions regarding the surgical technique.

The inclusion criteria were patients with late-stage knee arthritis. We excluded from our study patients with revisions and cases requiring a more significant constraint than a posterior stabilized TKA (constrained or hinged knee). We also excluded patients with acute coronary diseases, neurological diseases, infectious conditions, coagulation disorders, and a history of deep vein thrombosis or pulmonary embolism.

This paper was approved by the "Foisor" Orthopaedics Clinical Hospital Ethics Committee of Bucharest, Romania, approval number 6384/2021. Written informed consent was obtained from all patients included in this study. The procedures were conducted by international ethical standards and the 1964 Helsinki Declaration.

A radiological assessment was performed using plain X-rays, including an anteroposterior, lateral, and full weight-bearing lower limb, to develop proper preoperative digital planning.

2. Surgical Technique

All TKA procedures were performed according to a standard protocol by a single highly experienced orthopedic surgeon in our institution, specialized in TKA. The implant of choice was the Zimmer Biomet NexGen implant system. Preoperatively, 1 g of tranexamic acid was administered to all cases, and an additional 1 g after the procedure. All patients received spinal anesthetic with a femoral nerve block. A tourniquet was installed after three minutes of elevating the lower limb and was inflated up to 320 mm Hg before the incision and deflated after the implantation to perform hemostasis. We used a midvastus approach, an extramedullary tibial guide, an intramedullary femoral guide, and a measured resection technique. Wound closure was performed in a layered fashion and all patients received a deep drain. The drain was clamped for three hours and then released and removed 24 hours after surgery. The rehabilitation protocol was similar for both groups and began on the first day after surgery. Physical therapy was continued either at home or in a specialized clinic. All cases received Heparin for deep vein thrombosis prophylaxis for 30 days.

We recorded preoperative data, which included age, gender, knee range of motion, hemoglobin values, bleeding, and comorbidities. Knee function was measured using the Knee Society Knee Score (KSKS). The amount of bleeding was assessed by measuring the postoperative hemoglobin and bleeding during and after the surgery. Intraoperatively we measured the amount of blood aspiration by taking into account the amount of physiological serum used for lavage and the operative time. After the surgical procedure, we measured the amount of blood aspirated through the drains and hemoglobin. All complications were recorded throughout the study. For the functional evaluation, we measured flexion, extension, the Visual Analogue Scale (VAS), and KSKS score after 4 and 12 weeks. A blind independent observer evaluated all the measurements.

3. Outcome measures

The Visual Analogue Scale is a measure used to evaluate the patient's perspective of pain level. It may be dependent on the patient's mental status but is very frequently used to correlate with knee function evaluation [17,18].

The KSKS contains questions in 2 sections: knee score (pain, range of motion, stability) and function (walking distance, ability to climb stairs, walking aids) [19]. Both measures were provided to patients for answering in the hospital and during follow-up visits.

4. Statistical analysis

All values were calculated as mean values ± standard deviation. The statistical analysis was developed using the Student t-test and Mann-Whitney U test for comparison between groups. A p-value lower than 0.05 was considered statistically significant. The data was analyzed for Windows OS using SPSS version 28.0 (SPSS Inc., Chicago, IL).

RESULTS

We recorded 180 cases split into two even groups. The patient characteristics are displayed in Table 1.

The blood loss measured during the surgical procedure was 367.77 ± 115.71 mL for the total synovectomy, while the second group recorded 295.55 ± 106.17 mL of blood loss ($p < 0.05$). Regarding postoperative bleeding, the TS group aspirated 533.77 ± 281.65 mL, which was significantly higher than the PS group, where we recorded an aspiration of 404.44 ± 211.55 mL (Table 2).

Table 1: Baseline characteristics of the study groups

	Total synovectomy	Partial synovectomy	p-value
Age (years)	70.41±7.25	70.8±7.23	0.71
Gender (M/F)	41/49	44/46	0.77
Preoperative hemoglobin (g/dL)	13.24±1.22	13.22±1.18	0.90

Table 2: Postoperative parameters of the study groups

	Total synovectomy	Partial synovectomy	p-value
Intraoperative bleeding (mL)	367.77±115.71	295.55±106.17	<0.05
Postoperative bleeding (mL)	533.77±281.65	404.44±211.55	<0.05
Postoperative hemoglobin (g/dL)	11.43±1.26	11.88±1.22	<0.05
VAS[1] score (4 weeks)	3.39±1.50	3.79±1.32	0.058
VAS score (12 weeks)	1.3±1.01	1.41±0.89	0.43
KSKS[2] score (4 weeks)	82.28±4.09	82.42±4.46	0.83
KSKS score (12 weeks)	87.9±3.7	88.33±4.11	0.47
Operating Room time (min.)	96.5±7.93	92.2±6.37	<0.05

[1] VAS=Visual Analogue Scale; [2] KSKS=Knee Society Knee Score

The mean preoperative hemoglobin was 13.24 ± 1.22 g/dL for the TS group and 13.22 ± 1.18 g/dL for the PS group ($p = 0.90$). Postoperatively, a statistically significant decrease was recorded in the two groups, the hemoglobin dropping to 11.43 ± 1.26 g/dL and 11.88 ± 1.22 g/dL, respectively, ($p < 0.05$). However, after four weeks, the VAS score was 3.39 ± 1.50 in the TS group and 3.79 ± 1.32 in the PS group, while KSKS was 82.28 ± 4.09 and 82.42 ± 4.46, respectively. Both scores' differences between groups were not significant. At the three months follow-up, both parameters showed improvements for both groups. VAS score was 1.3 ± 1.01 for the TS group, while PS patients had a score of 1.41 ± 0.89. ($p = 0.43$) KSKS score showed no statistically significant differences after three months, the results being 87.9 ± 3.7 and 88.33 ± 4.11, respectively ($p = 0.47$). However, we recorded significant differences regarding the operative room time between groups: 96.5 ± 7.93 minutes for the TS group and 92.2 ± 6.37 minutes for the PS group, respectively ($p < 0.05$).

Regarding complications, we recorded 7 cases of deep vein thrombosis in the total synovectomy group and 5 cases in the partial synovectomy group.

We recorded wound complications in three cases in the first group and two patients in the second group. Also, we noticed hemarthrosis following drain removal in 20 cases that underwent total synovectomy and 5 cases with partial synovectomy**.**

DISCUSSION

The synovial tissue is regarded as a critical component in the locomotor function [20,21]. The synovial tissue of the knee joint plays multiple roles, including the secretion of synovial fluid that lubricates the joint, providing nutrients to the articular cartilage, protection against infection, and removal of waste products from the joint. The aforementioned functions are responsible for the maintenance of the health and proper functioning of the knee joint. On the other hand, progressive joint degeneration, which leads to osteoarthritis, is caused by the involvement of bone, cartilage, and synovial pathological processes [21,22]. For this reason, synovectomy is performed to relieve pain or to attempt the prevention of cartilage and/or bone destruction and to improve knee function [23,24].

During a total knee arthroplasty, total synovectomy may be performed for different reasons. One reason is to remove any inflamed or diseased synovial tissue that may be present in the joint, with the aim of improving joint function and reducing pain and inflammation. Another reason is to prevent the formation of a pseudo capsule, a thick layer of scar tissue that can form around the artificial joint and cause complications. However, total synovectomy may also have drawbacks, such as an increased risk of infection and reduced lubrication and nutrition of the articular cartilage [21,22]. The decision to perform a total synovectomy during a total knee arthroplasty should be taken individually, for each patient, by weighing the potential benefits and risks. Furthermore, proper planning of the procedure is essential to ensure shorter operating times and faster recovery; this includes digital radiological planning, choosing the ideal implant type and model, and controlling the patient risk factors [25-27].

Our study aimed to evaluate the influence of synovectomy on postoperative results and blood loss following total knee replacement. The intraoperative and postoperative blood loss was found to be significantly higher after total synovectomy compared to the partial synovectomy group. We found variable results regarding average blood loss in the literature, which ranged between 300 and 2500 mL [12,28-30]. This variability may be explained by the different surgical techniques, thromboprophylaxis treatments, or implant types that were applied. In our paper, the total synovectomy group had a blood loss from drains of 533.77 ± 281.65 mL for the total synovectomy group compared to the second group, which had 404.44 ± 211.55 mL blood loss. We consider this to be one of the main reasons behind the preference of some surgeons to avoid total synovectomy.

Our study also revealed a significantly lower postoperative hemoglobin level after synovectomy. This result was also recorded in other papers [12,21,31]. However, some studies concluded that even though the bleeding rates are higher, the blood transfusion threshold is not reached when total synovectomy is performed, therefore the two surgical techniques do not yield statistically significant differences in this regard [15,21].

Another significant result of this study was that total synovectomy demonstrated some postoperative improvements but these were not statistically significant compared to the other group and did not show any differences regarding pain relief, despite the considerable blood loss difference. It is well known that the synovium, as well as other articular structures like muscles, joint capsules, or ligaments, is well-innervated and could be a source of pain in osteoarthritis [32,33]. Even though synovectomy reduces knee pain, especially in cases with pathological synovial tissues, the VAS score in our study did not show any significant differences during the follow-ups. Also, the KSKS score showed no significant differences after 4 weeks or after 12 weeks. This result is also reported by other authors who also recorded increased concealed bleeding, higher drainage, and longer operative time in patients that underwent total synovectomy [12]. Moreover, similar studies evaluating the quality of life and complications recorded no significant improvements regarding these parameters [34].

Literature data have indicated that total synovectomy during total knee arthroplasty may be linked to an increased incidence of certain complications such as deep vein thrombosis, hemarthrosis, and wound complications [12,21,33-37]. However, it is essential to note that the available data is currently limited. Therefore, additional investigations with a larger sample size are required to establish a more robust statistical correlation on this subject. Despite this observation, it should be noted that individual patient characteristics and other factors may also contribute to the occurrence of these complications.

One major limitation of our study is that it was conducted in a single center, which may limit the generalization of our results to other study populations. Additionally, we did not evaluate hematocrit levels or blood transfusion requirements, which are important factors that could reveal further associations between total synovectomy and blood loss. Furthermore, we acknowledge that more extended follow-up periods could be beneficial in the thorough evaluation of the functional outcomes and risk of synovial recurrences associated with total synovectomy during total knee arthroplasty. Additionally, it is important to note that our study did not assess the risk of other potential complications that could arise from this procedure. Therefore, while our study provides important insights into the potential risks and benefits of total synovectomy during total knee arthroplasty, additional research with a larger sample size and more extended follow-up periods are needed to fully understand the implications of this procedure for patients undergoing knee arthroplasty.

CONCLUSIONS

Patients with total synovectomy associated with total knee arthroplasty experienced a notably more significant amount of blood loss and lower postoperative hemoglobin levels than the control group. However, no statistically significant differences were observed between the two groups in terms of knee function and pain level. Further multicenter studies with longer follow-up times are required to more comprehensively assess the potential complication rate and risk of synovial recurrence associated with total synovectomy during total knee arthroplasty. Ultimately, more comprehensive research is required to determine the optimal approach to synovectomy and to provide the most beneficial outcomes for patients undergoing total knee arthroplasty.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Authors' contribution

M.-A.P. and L.L.P. planned the clinical study and contributed to the concept and design of the study. M.E.G., D.C.C., and A.L. contributed to the data analysis and interpretation as well as to the translation and the critical revision of important intellectual content. C.S. and R.C. contributed to the writing of the manuscript and performed revision, language, and textual editing of the final version. All authors contributed to the original draft preparation of the manuscript. All authors have read and agreed to the published version of the manuscript.

Patient consent for publication

Informed consent was obtained from all subjects involved in the study.

Ethics approval and consent to participate

All procedures performed in this paper were by the 1964 Helsinki Declaration and its later amendments or comparable ethical standards and according to the national ethical standards. The study received approval from the "Foisor" Orthopaedics Clinical Hospital Ethics Committee of Bucharest, Romania, approval number 6384/2021 (date of approval 10th of December 2021). Informed consent was obtained from all individual participants included in the study.

Abstract: *There are conflicting data on the effects of magnesium on hypertension in the literature. Therefore we aim this study to investigate whether there is a relationship between serum magnesium levels and hypertension in newly diagnosed. This is a case-control study. The patients were selected from the records of patients who applied to the family medicine outpatient clinic between June 2016 and May 2017. A total of 276 patients, 68 patients with newly diagnosed hypertension in the case group and 208 patients without any disease in the control group were included in the study. Binary logistic regression analysis was performed between the case and control groups. The odds ratio for magnesium was 0.1 (0.012-0.810). When the value of the magnesium variable increases by 1mg/dl, the risk of hypertension decreases by 90%. However, in the presence of magnesium as an independent variable, the predictability rate of our model was expected to increase but decreased. The odds ratio for age was 1.14 (1.092-1.186). The odds ratio for exercise was 0.18 (0.03-0.99). The odds ratio for glucose was 1.03 (1.001-1.065). In our study that magnesium deficiency causes an increased risk of hypertension, the predictability rate of our model was expected to increase instead of decrease. These findings show that a cause-effect approach or incidental association cannot explain the relationship between magnesium and hypertension*.

Keywords: *hypertension; magnesium; age; exercise; glucose*

INTRODUCTION

The prevalence of hypertension continues to increase globally [1]. The prevalence of hypertension in the adult population in the world is 31% [2]. For over forty years, the causes of most hypertensive diseases have been unknown and are defined as primary or essential hypertension. Secondary causes are accepted as 5-10% [3].

Recently, risk factors such as age, sex, race, family history, genetic composition, obesity, excessive salt intake, inactivity or lack of exercise, high-fat diet, tobacco use, and alcohol consumption have been proven to lead to the development of hypertension [4].

Magnesium (Mg) can be found in the fourth sequence in the human body and the second after potassium in the intracellular area [5]. Magnesium is an essential cation playing a crucial role in many physiological functions. It is critical in energy-requiring metabolic processes, protein synthesis, membrane integrity, nervous tissue conduction, neuromuscular excitability, muscle contraction, and hormone secretion [6]. Given the role of magnesium in calcium and potassium transport, cell signaling, energy metabolism, genome stability, DNA repair, and replication, it should be expected that hypomagnesemia is associated with many diseases, including neurological disorders, osteoporosis, diabetes, coronary heart disease, and hypertension [7].

Magnesium levels were lower in white hypertensives than in normotensives, while no significant difference was found in black hypertensives compared to normotensives [8]. It has been shown that those with essential hypertension have a significantly higher intra-erythrocytic magnesium level than healthy individuals [9]. A systemic review and meta-analysis study suggested no relationship between serum magnesium and hypertension but that dietary magnesium supplementation reduces blood pressure [10]. Magnesium deficiency was found to be responsible for calcium and magnesium disorders in those with pregnancy-induced hypertension, and magnesium sulfate therapy was effective in these patients [11]. In a meta-analysis of twelve studies, a reduction in diastolic blood pressure was observed, while a decrease in systolic blood pressure was not observed [12]. Again, a meta-analysis of 20 studies found a reduction in systolic blood pressure while no change in diastolic blood pressure [13]. A meta-analysis of 22 studies noted a reduction in both systolic and diastolic blood pressure [14].

The fact that there are conflicting data on the effects of magnesium on hypertension in the literature shows a need for research on this subject. For this purpose, we wanted to evaluate magnesium levels in patients with newly diagnosed hypertension. This study aims to investigate whether there is a relationship between serum magnesium levels and hypertension.

MATERIALS AND METHODS

Study Design

This study is a case-control study. The sample size was determined for logistic regression analysis, considering the number of seven independent variables, such as age, gender, body mass index (BMI), smoking, alcohol consumption, exercise status, and magnesium. For each group, using the power analysis method, the minimum sample size of at least 48 which is needed to detect a significant difference when taken into account at 0.05 type-I error (Alpha), 0.35 effect size, 0,80 power (1-beta).

Population selection

The patients included in the study were selected from those who applied to the family medicine outpatient clinic between June 2016 and May 2017 from the hospital information system and patient records. Sixty-eight people with hypertension constituted the case group. Two hundred-eight people without hypertension formed the control group. The control group was selected considering demographic characteristics such as age and gender.

Inclusion and exclusion criteria

Among the patients tested for magnesium at the time of admission, patients with hypertension newly diagnosed were included in the case group, and those with no chronic disease and no medication were included in the control group. The study did not include those with any illness and drug use before the application, those with a previous hypertension diagnosis and treatment, and those without magnesium checked at the time of application.

Statistical analysis

All statistical analyses were performed using IBM SPSS Statistics (V25). A P-value below 0.05 was considered statistically significant. In the data expression, categorical data, numbers and percentages, and numerical data were expressed with averages and standard deviation. The distribution of demographic data was analyzed by frequency tests, comparison of categorical data by chi-square test, and comparison of numerical data by independent sample t-test. The stepwise enter model was used in the binary logistic regression test to evaluate the effect of magnesium on hypertension. Skewness and kurtosis analyses were used to conform the data to the normal distribution.

Ethical Considerations

Ethical approval was obtained from the İstanbul Training Research Hospital Clinical Research Ethics Committee (Decision no. 14.10.2022, 318).

RESULTS

A total of 276 people, including 68 cases and 208 control groups, were included in the study. There was no found difference between those with hypertension and those without it in terms of sex, smoking, and alcohol consumption. However, the proportion of those without exercise was found to be lower in the hypertension group (Table 1).

Table 1: Comparison of the case and control groups in terms of gender, smoking, alcohol consumption, and exercise status

Characteristics of participants		Hypertension N (%)			
		No	Yes	Total	p
Gender	Women	149 (71.6)	52 (76.5)	201 (72.8)	0.530
	Men	59 (28.4)	16 (23.5)	75 (27.2)	
Smoking	No	167 (80.3)	58 (85.3)	225 (81.5)	0.472
	Yes	41 (19.7)	10 (14.7)	51 (18.5)	
Alcohol	No	204 (98.1)	68 (100.0)	272 (98.6)	0.575
	Yes	4 (1.9)	0 (0.0)	4 (1.4)	
Exercise	No	168 (80.8)	66 (97.1)	234 (84.8)	< 0.001*
	Yes	40 (19.2)	2 (2.9)	42 (15.2)	

Chi-Square Tests: The statistically significant difference was accepted as p < 0.05

The average age and BMI were found to be higher in the group with hypertension. Additionally, glucose, total cholesterol, triglycerides, and LDL- cholesterol (LDL-C) were found to be increased in the case group. Magnesium levels were found to be higher in the control group than in the case group (Table 2).

Table 2: Comparison of case and control groups in terms of age, body mass, and biochemical parameters

	Hypertension			
	No	Yes		
	Mean ± SD		t.	p
Glucose (mg/dl)	95.25 ± 11.04	107.79 ± 15.96	-6.02	< 0.001*
Cholesterol (mg/dl)	206.55 ± 44.32	229.43 ± 35.59	-3.86	< 0.001*
Triglycerides (mg/dl)	111.96 ± 61.58	154.07 ± 60.27	-4.92	< 0.001*
HDL-C (mg/dl)	54.55 ± 12.66	52.68 ± 7.40	1.49	0.137
LDL-C (mg/dl)	129.35 ± 37.07	143.49 ± 29.66	-3.19	0.002*
Calcium (mg/dl)	9.47 ± 0.46	9.54 ± 0.43	-1.11	0.266
Magnesium (mg/dl)	1.99 ± 0.19	1.92 ± 0.15	2.82	0.005*
Sodium (mmol/L)	139.14 ± 1.99	145.24 ± 32.97	-1.52	0.133
TSH (mIU/L)	1.91 ± 1.29	1.90 ± 1.20	0.06	0.950
Vitamin B12 (ng/L)	231.69 ± 127.26	207.32 ± 90.38	1.73	0.085
Vitamin D (ng/ml)	20.08 ± 10.69	19.32 ± 9.60	0.52	0.602
Age (years)	39.69 ± 12.80	59.71 ± 11.65	-11.42	< 0.001*
BMI	25.83 ± 4.48	29.50 ± 6.25	-4.47	< 0.001*

*SD: Standard Deviation; BMI: Body Mass Index; *Independent sample t-test is significant at the 0.05 level (2-tailed)*

Binary logistic regression analysis was performed by considering the different parameters between the case and control groups. In addition to the magnesium, age, exercise, BMI, glucose, triglyceride, and LDL-C variables which were different between the case and control groups, gender and sodium variables were also included in the analysis according to the literature [4]. Total cholesterol was not included in the study because it is affected by LDL-C and triglyceride.

In the analysis in which only magnesium as an independent variable was added, the model is insignificant because the Cox-Snell R2 and Nagelkerke R2 values are smaller than the 0.2 value. However, the model is significant when other independent variables are added. Except for the step in which triglyceride was added, the model's goodness of fit is acceptable since the p-values are bigger than 0.05 in the Hosmer-Lemeshow test. Changes in -2 Log Likelihood values (Chi-square, $p < 0.05$) are significant in magnesium, age, exercise, and glucose steps.

These results show that the logistic regression analysis is generally valid (Table 3).

Table 3: Distribution of data showing the validity of the logistic regression analysis

Metod=Enter: stepwise	-2 Log Likelihood	Chi-square	P	Cox and Snell R Square	Nagelkerke R Square	Hosmer and Lemeshow Test	Predicted percentage
Beginning	308.192						75.4
+ Magnesium	299.999	8.193	0.004*	0.029	0.043	0.150	74.6
+ Age	194.958	105.041	< 0.001*	0.337	0.500	0.493	82.6
+ Exercise	186.608	8.350	0.004*	0.356	0.530	0.642	81.9

+ Triglycerides	179.265	0.015	0.901	0.373	0.555	0.044*	83.3
+ LDL-C	178.064	1.201	0.273	0.376	0.559	0.744	82.6
+ Sodium	178.059	0.005	0.944	0.376	0.559	0.746	82.6

**The statistically significant difference was accepted as $p < 0.05$*

The odds ratio for magnesium was found to be 0.1 (0.012-0.810). When the value of the magnesium variable increases by 1mg/dl, the risk of hypertension decreases by 90% (Table 4). However, in the presence of magnesium as an independent variable, the predictability rate of our model was expected to increase but decreased (Table 3). The odds ratio for age was found to be 1.14 (1.092-1.186). When the value of the age variable increases by one unit, the risk of hypertension increases by 1.14 times. The odds ratio for exercise was found to be 0.18 (0.03-0.99). When the reference group is taken as those with non-exercise, the risk of hypertension was found to be 82% less in those with exercise. The odds ratio for glucose was found to be 1.03 (1.001-1.065). When the value of the glucose variable increases by 1 mg/dl, the risk of hypertension increases by 1.03 times (Table 4).between vitamin D and total cholesterol and LDL-C in the young age group. However, serum vitamin D had no significant correlation with serum glucose, triglyceride, HDL-C, calcium, magnesium, sodium, TSH levels, and BMI scores (Table 4).

Table 4: Logistic regression analysis showing the relationship between hypertension and variables of magnesium, age, exercise, gender, BMI, glucose, triglyceride, LDL-C, and sodium

Hypertension[a]	B	SE	Wald	P	Risk (Odds) coefficient	95% C.I.for (Exp B)	
						Lower	Upper
Magnesium (mg/dl)	-2.325	1.079	4.645	0.031*	0.1	0.012	0.810
Age (years)	0.129	0.021	37.532	< 0.001*	1.14	1.092	1.186
Exercise (1: -/+)	-1.723	0.874	3.882	0.049*	0.18	0.032	0.991

DISCUSSION

The fact that the age and BMI values, glucose, total cholesterol, triglycerides, and LDL-C levels are high in those with hypertension and the low rate of exercisers shows that the study groups are compatible with the general population.

In our study, magnesium levels were lower in those with hypertension. When the value of the magnesium variable increases by 1mg/dl, the risk of hypertension decreases by 90%. However, in the presence of magnesium as an independent variable, the predictability rate of our model for hypertensive patients decreased, while it was expected to increase [2]. In two meta-analysis studies involving seven and 11 studies, it has been suggested that magnesium supplementation provides a significant, albeit small, decrease in blood pressure [15,16]. In a meta-analysis in which thirty-four studies were evaluated, it was found that there was a decrease in both systolic and diastolic blood pressure [17]. A recent meta-analysis study claimed that oral magnesium supplementation does not affect blood pressure in normotensives and controlled hypertensives but reduces blood pressure in uncontrolled hypertensives [18]. In addition, there was no difference in magnesium levels between those with hypertensive crisis and the control group [19]. However, in light of these contradictory findings, considering that the number of participants in meta-analysis studies is high, it is a point that should not be overlooked that statistical significance will be high, even if there is no significance in reality.

In our study, it was found that when the value of the age variable increased by one unit, the risk of hypertension increased by 1.14 times. In our working model, the probability of predicting hypertensive patients in the presence of magnesium and age is relatively high. This result indicates that the age variable is an important risk factor. In the literature, age is recognized as a risk factor for hypertension [4]. Studies have been reported showing that magnesium decreases with age [20,21]. It has been suggested that this relationship may be related to decreased absorption with age and slower kidney reabsorption [22,23]. In addition, recent reports indicate that many Americans, especially older people, do not consume the recommended daily amount of magnesium [24]. In countries with high incomes, the rate of hypertension is lower than in poor countries [2]. Again, it is stated that an unhealthy diet causes hypertension [25]. All these findings and literature information suggest that the relationship between magnesium and hypertension may be an incidental association.

Our study found that the risk of hypertension decreased by 82% in those who exercised. In the literature, it is accepted that inactivity or lack of exercise is a risk factor for hypertension [4]. It is stated that regular exercise causes a decrease in blood pressure of 5 mmHg [26]. In addition, emphasis has been placed on the curative effect of both aerobic and moderate-weight exercise on hypertension [27]. Aerobic exercise is assumed to positively affect hypertension by reducing oxidative stress [28]. A recent meta-analysis indicates that aerobic exercise is an effective adjunctive treatment method for lowering ambulatory blood pressure in hypertension patients receiving drug therapy [29].

Our study found no relationship between body mass index and hypertension. However, when the value of the glucose variable increased by one unit, the risk of hypertension increased 1.03 times, albeit very slightly. Obesity is accepted as a risk factor for hypertension in the literature [4,30]. Mechanisms of obesity causing hypertension are explained by the activation of the sympathetic nervous system activated by hormones such as leptin, insulin, melanocortin, and the activation of the renin-angiotensinogen system due to oxidative effects caused by proinflammatory cytokines released as a result of dyslipidemia [31]. Many pathophysiological mechanisms explain the relationship between diabetes and hypertension. These mechanisms are mainly hyperinsulinemia-mediated sympathetic activation, hyperglycemia-induced sodium-fluid retention, the stimulatory effect of hyperglycemia on the renin-angiotensin-aldosterone system, and increased insulin resistance as a result of oxidative stress [32,33].

An increased risk of type-2 diabetes and increased LDL-C levels were found in low magnesium [34]. It has been suggested that the positive effects of magnesium on diabetes occur by inhibiting oxidative stress [35]. It is also stated that the primary pathology in gestational hypertension in which magnesium sulfate is used in the treatment is oxidative stress [36]. The positive effects of regular and aerobic exercise on oxidative stress and its curative effects on diabetes and obesity have been emphasized [37]. Both magnesium deficiency and oxidative stress have been identified as pathogenic factors in aging and age-related diseases. Additionally, severe magnesium deficiency has been shown to increase oxidative stress in experimental animals [38]. In light of these findings, it seems complicated to define the relationship of magnesium with hypertension without fully elucidating the complex effects of oxidative stress on hypertension.

CONCLUSIONS

As a result, it was found in our study that magnesium deficiency causes an increased risk of hypertension. However, in the presence of magnesium as an independent variable, the predictability rate of our model was expected to increase but decreased. These findings show that the relationship between magnesium and hypertension cannot be explained only by a cause-effect connection or incidental association. This may explain the reason for the conflicting results in the literature. More detailed analyzes are needed in this regard.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results. This research received no external funding.

Authors' contribution

All authors made substantial contributions to the conception or design of the work or the acquisition, analysis, or interpretation of data for the work. All authors have read and agreed to the published version of the manuscript.

Patient consent for publication

Because of the retrospective study, patient consent was not obtained.

Ethics approval and consent to participate

Ethical approval was obtained from the İstanbul Training Research Hospital Clinical Research Ethics Committee (Decision no. 14.10.2022, 318).

Abstract: *On February 24, 2022, the Russian-Ukrainian war began, in which hundreds of thousands of military personnel are participating. Almost all military personnel experience combat stress. In our opinion, the most fully reflecting the occurrence of stress in humans, including combat stress in military personnel, is the conservation of resource theory proposed by S. Hobfoll. According to this theory, stress occurs when: central or key resources (health, well-being, family, self-esteem, and a sense of purpose and meaning in life) are threatened with loss, are lost, or cannot be retrieved following significant effort. Combat stress in military personnel can manifest itself in the form of negative manifestations of the psychological, physical, psychophysiological, and behavioral register. The most effective system for the prevention and control of combat stress among military personnel was developed in the US Army. Such a program should contain medical and psychological work activities carried out in three stages: preparatory (before performing combat missions), the stage of direct performance of tasks in the combat zone, and the final stage (after completing tasks upon returning to permanent deployment points).*

Keywords: *stress, combat stress, military personnel, fighting, COSC*

INTRODUCTION

There are few areas of contemporary psychology that receive more attention than stress [1,2]. This literature reflects researchers' belief that stress is a major factor affecting people's lives, is intimately tied to mental health, and is very possibly linked with many problems of physical health [1]. The interest in stress has also caught the attention of the popular press, illustrating that stress is of concern to the lay public as well as the academic community [3]. However, despite the breadth of interest in the problem of stress, there is little research to substantiate the relevant theories [2]. But in psychology, as in other sciences, it is difficult to create a sincere body of knowledge without a clear theoretical foundation, because there are no definite limits to the theory that can be denied [4].

An analysis of scientific sources on the subject of combat stress has shown that a lot of applied research has been carried out to solve this rather complex problem. This is because the last fifty years have been characterized by a significant increase in local and regional armed conflicts in the world [5-7]. The localization, time, nature, goals, the pace of hostilities, and military operations varied greatly during this period. But, as a rule, the majority of military personnel in their military career took part only in a series of combat deployments [8].

However, in the 21st century, not a single country, except Ukraine, has faced the armed aggression of the Russian Federation, and a large-scale war has been going on for more than a year. Hundreds of thousands of troops from both sides are taking part in the fighting. Almost all Ukrainian servicemen experience combat stress [9-11]. These circumstances, as well as the duration and complexity of staying in extreme (combat) conditions, put forward high demands on the mental health, army values and motivation of military personnel, as well as on their psychological qualities and the adequacy of behavior for this activity [12-18]. Despite the high motivation to conduct combat operations, the improvement of military professional training and psychological preparation, some military personnel have problems with mental health, manifested by the development of acute stress reactions, post-traumatic stress disorders (PTSD), as well as addictive and delinquent behavior, an increase in suicidal manifestations [19-25].

Similar mental, physical, and behavioral health problems have occurred in US and coalition forces during and after combat deployments in Iraq and Afghanistan [5-7,26-30]. In combatants, these disorders manifested in persistent sleep disturbances, headaches, fatigue, and other symptoms associated with the influence of various stress factors in the combat environment, as well as the occurrence of more complex and severe disorders such as PTSD, traumatic brain injury and depression [31-33].

The conducted studies revealed that the significance of the influence on the psyche of military personnel and the development of the consequences of experiencing combat stress were determined by: factors of the combat situation; individual psychological characteristics of a person; the level of professional and psychological preparation for the conduct of hostilities; the nature and level of motivation of military personnel; the influence of combat stress factors on the further life of military personnel, etc. [9,20,28,34,35].

The objective of this study

The purpose of the article was to systematize scientific research on the problem of stress, combat stress, to study the modern system of mental health care for military personnel of the leading NATO partner countries, and to determine the main directions for improving the Ukrainian system for the prevention and control of combat stress among military personnel.

BASIC STRESS THEORIES

All theories of stress, in particular, combat stress, are based mainly on medical, biological, and psychological studies that reflect the processes of a distinct reaction of the human body to stress. In general, the term “stress” was borrowed by researchers from physics: it was previously believed that people are in some sense similar to physical objects, such as metals, resisting moderate external forces, but losing their stability at some point of higher pressure [1]. Walter Cannon was probably the first researcher to apply the concept of “stress” to humans in these kinds of terms [36]. He concluded that a person can resist initial stressors of moderate strength or lower-level negative factors that cause stress. However, prolonged or more severe stressors will lead to disruption of the body’s biological systems [36].

W. Cannon’s research on stress was continued and developed by Hans Selye. He described stress as a reaction (organized defense) of the body to non-specific harmful agents and called it the “general adaptation syndrome” [37]. According to the author’s definition, the general adaptation syndrome is the body’s response to severe damage by non-specific harmful agents (for example, exposure to cold, surgical shock, excessive physical exertion, or intoxication with sublethal doses of various drugs) and it does not depend on the nature of the damaging agent [37]. Thus, the protective role of the general adaptation syndrome consisted in the formation of nonspecific resistance of the organism to pathogenic agents, regardless of their nature. The researcher believed that there is a response of the body to external factors, which go through three stages in succession: anxiety (anxious response), resistance, and exhaustion [38].

Another direction in the study of the mechanisms of development of stress has already taken into account not only responses to stressors but also directly stressful events, as well as individual differences in their assessment. Spielberger suggested that certain events are stressful if they are thought to be threats to the physical self or the phenomenological self [39]. He proved that although individuals with different personalities responded some-what uniformly to physical threats, people’s responses to ego-threats were related to personality traits. In particular, Spielberger noted that people with high trait anxiety tended to react with state elevations in anxiety to ego-threat, whereas those who were low in trait anxiety tended to be comparatively impervious to ego-threats. Thus, the researcher concluded that it is not the stimulus and not the assessment that is important, but their specific interaction. This three-step approach was a conceptual leap for stress researchers but rarely followed up in further research. Instead, many researchers have reverted to models that only assessed stress, almost completely ignoring actual environmental or personality traits; others reflected only personality characteristics, while others remained tied only to the model’s stimuli.

In modern studies of the problem of stress, the homeostatic and transactional models of stress are most often used. The homeostatic model is presented in detail by McGrath [40] but is based in large part on the work of Lazarus [41]. According to research results, McGrath proposed the definition of stress as “a significant imbalance between the needs of the environment and the ability to respond to the body” [40, p. 17].

In 1966, the concept of cognitive appraisal was proposed by Richard Lazarus [41]. According to this theory, stress is perceived as the imbalance between the demands placed on the individual and the individual's resources to cope [2]. The transactional model of stress and coping contended that a person's capacity to cope and adjust to challenges and problems is a consequence of transactions (or interactions) that occur between a person and their environment. The authors defined stress as "a particular relationship between the person and the environment that is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being" [2, p. 19].

However, according to Hobfoll, these models and their definitions have a number of shortcomings [1]. First, the author notes, these definitions state that stress is not the product of an imbalance between objective demands and the ability to respond, but is the result of the perception of these factors. Secondly, the consequences of failure should be perceived as very important for a person. Third, McGrath suggested that imbalances might manifest as underutilization rather than overload, i.e. too little need for the ability to cope with stress [1].

In our opinion, one of the leading modern paradigms of the problem of stress, which is used by both scientists and practical psychologists in their work, is the conservation of resource theory proposed by Stephen Hobfoll. According to this theory, stress arises from motivation that encourages people to both maintain their current psychological resources and seek new opportunities [1]. Its main principle is that individuals strive to obtain, retain, foster, and protect those things they centrally value. The main postulates of this theory are understanding that stress occurs when: (a) central or key resources are threatened with loss, (b) central or key resources are lost, or (c) there is a failure to gain central or key resources following significant effort [1].

Essentially, the conservation of resource theory is a motivational theory that explains much of human behavior in terms of the evolutionary need to obtain and maintain resources for survival, which is central to the genesis of human behavior [42]. Resources are defined as those objects, personal characteristics, conditions, or energies that are valued by the individual or that serve as a means for the attainment of these objects, personal characteristics, conditions, or energies. According to the authors, people must acquire and maintain both strong personal characteristics and social ties. Thus, people must use key resources not only to respond to stress but also to create a certain amount of supportive resources in case of future needs. Moreover, the acquisition and maintenance of personal, social, and material resources create in people, families, and organizations the feeling that they are able to cope with stressful situations.

According to Hobfoll, a critical tenet conservation of resource theory is that individual value is secondary to what is most valued and universal to people. Typically, these valuable resources are health, well-being, family, self-esteem, and a sense of purpose and meaning in life [42]. How these evaluations are expressed may vary across cultural backgrounds but always reflects the same basic elements. The conservation of resource theory, in general, explains the mechanisms of development and transformation of the psychological safety of personality in military personnel during activities under different conditions [43].

DEFINITION OF COMBAT STRESS

An analysis of scientific research has shown that there is no generally accepted definition of the "combat stress" construct: depending on the field of its study (medicine, biology, psychology, sociology, other social sciences), there are many definitions of this category. Specialists who study stress in military personnel during combat operations suggest using such constructs as combat mental trauma, combat stress, combat mental pathology, post-traumatic stress disorders, and others definitions.

The official website of the US Department of Defense provides the definition of combat stress, also known as battle fatigue, which is a common response to the mental and emotional strain that can result from dangerous and traumatic experiences. It is a natural reaction to the wear and tear of the body and mind after extended and demanding operations [44]. Combat stress reaction (CSR) is a term used within the military to describe acute behavioral disorganization seen by personnel as a direct result of the trauma of war. CSR is an acute reaction that includes a range of behaviors resulting from the stress of battle that decrease the combatant's fighting efficiency. The most common symptoms are fatigue, slower reaction times, indecision, disconnection from one's surroundings, and the inability to prioritize. The combat stress reaction is generally short-term. The US Army uses the term/acronym COSR (Combat Stress Reaction) in official medical reports. This term can be applied to any stress reaction in the military unit environment. Many reactions look like symptoms of mental illness (such as panic, extreme anxiety, depression, and hallucinations), but they are only transient reactions to the traumatic stress of combat and the cumulative stresses of military operations [45].

Blinov defines combat stress as a reaction of the psyche to a threat to life and health in the form of a process of experiencing mental states at the stages of adaptation using the resource potential [9].

Snedkov makes a distinction between combat stress, combat psychic trauma, and combat psychic pathology [46]. Under combat stress, the author understands “a multilevel process of adaptive activity of the human body in a combat situation, accompanied by a tension in the mechanisms of reactive self-regulation and the consolidation of specific adaptive psychophysiological changes. Combat mental trauma is a pathological condition of the central nervous system, which is formed as a result of combat stress that exceeds the adaptive potential of a particular individual and forms the 'patos' of combat mental pathology. Combat mental pathology is a syndromic and nosologically structured clinical manifestation of combat mental trauma, the occurrence of which is due to the failure of compensation and the generalization of the pathogenetic mechanism” [46, pp. 28-29].

The authors of this article define the term “combat stress” as the process of the influence of combat situation factors on a soldier, accompanied by a decrease in the level of psychological safety of personality and the appearance of non-specific preclinical psychological manifestations, which together are presented by the concept of “combat psychological trauma of personality” or reach specific nosological symptoms of mental disorders, united in the concept of “combat mental trauma”. Combat stress in military personnel can manifest itself in the form of negative manifestations of the psychological, physical, psychophysiological, and behavioral register.

According to American mental health experts, combat and operational stress include all types of psychological and emotional stress that arise as a result of the dangers and requirements of performing tasks in warfare and other military operations [47]. The development of combat stress in military personnel, according to the authors, is directly influenced by: the intensity and duration of a traumatic event or situation; the level of psychological resilience and endurance of the individual; self-efficacy of a person (the ability to take certain actions to achieve a specific goal); collective effectiveness (general belief in the collective power to achieve the desired results); neurobiological factors (heredity, differences in the activity of the sympathetic nervous system, features of cortisol release in response to psychological stress, serotonin metabolism, etc.).

The effects of combat stress are mediated by a complex interaction between changing factors specific to each person and situation, as well as the dynamic interaction between them. Thus, managed moderately mild stressors can have a “hardening” or stress-modifying effect, when the body becomes less reactive to future stressors. Researchers have found that attention and arousal are essential for survival [30,48]. However, when they go beyond the maximum range, this is fraught with detrimental biological consequences: excessive and prolonged nervous excitement after an injury can increase the likelihood of developing PTSD [49].

EFFECTS OF COMBAT STRESS ON MILITARY PERSONNEL

American researchers have proposed a more detailed classification of stressors associated with external and internal factors [47]. They determined that combat-related external stressors included: self-injury; the killing of combatants; monitoring the death of people; death of colleagues; injury resulting in the loss of a limb. External stressors associated with military operations include prolonged exposure to extreme environmental conditions; reduced quality of life and communication resources for a long time; prolonged separation from important support systems (e.g., family); overseeing significant casualties across many missions (for example, overseeing the deaths of several unit comrades during combat operations). External physical stressors include exogenous (heat, cold, moisture, dust; vibration, noise, explosions); harmful odors (smoke, poison, chemical compounds); ionizing radiation; infected environment; physical work; poor visibility (bright light, darkness); difficult terrain; being at height. Physiological stressors that can cause combat stress include sleep deprivation; dehydration; malnutrition; poor hygiene; muscle and hypoxic fatigue; illness or injury; sexual frustration; the use of psychoactive substances (caffeine, alcohol, drugs); obesity; poor physical condition [47].

Mental (internal) stressors include cognitive; requirements or expectations, difficult decisions (combat rules); organizational dynamics and change; difficult choices or lack of it; work that goes beyond their own competence; preliminary failures. Emotional (internal) stressors are new to the unit; isolation, loneliness; fear and threats that cause anxiety (death, injury, failure, or loss); losses that cause grief (mourning); indignation, aggression, and frustrations, causing anger and a feeling of sadness; conflict (ambiguous) motives; inactivity that causes a feeling of sadness; religious confrontation or temptation to lose faith; interpersonal conflicts (in a unit or with comrades); family problems, nostalgia for home; victimization, sexual claims; observation of the battle, dead bodies; murder [47].

During deployment, military personnel is influenced by combat stressors (seeing dead human bodies, being attacked or ambushed, knowing someone who was injured or killed, and handling dead bodies) as well as operational stressors: long deployments, uncertain redeployment date, separation from families and lack of privacy [49,50,51]. Potentially morally compromising war circumstances, as noted by Wortmann et al., could involve prescribed roles (e.g. maiming and killing), proscribed behaviors (e.g. the use of excessive force or cruelty), bearing witness to the aftermath of violence or terror (e.g. handling or uncovering human remains) or being a victim of others' failures to uphold a moral code [52]. As a consequence, many service members suffer moral injury, characterized by guilt, shame, anger, social withdrawal, feelings of worthlessness, self-blame, and spiritual distress [33,52].

Effects of combat stress can also cause psychological trauma in military personnel, which can manifest itself both during the performance of combat missions and in the long-term period after their completion [7,30]. However, according to Born and Zamorski, deployment-related factors and exposure to potentially traumatic deployment experiences have the strongest and most consistent association with post-deployment mental health problems [53]. They may have short-term transient signs of the pre-nosological registry or more complex and severe somatic, psychiatric disorders, which should be well documented [27].

Recovery after exposure to combat stress can be facilitated by: a person's desire to open up and social support; the feeling that the social environment will accept the person's reactions with understanding and will encourage his openness; perception of the veteran as a hero or victim, but not as a victim; a sense of connection with God, a higher power, or a philosophical teaching; trauma-focused treatment to rethink negative reactions, clear intrusive memories, and help distinguish past from present threats [47].

Post-traumatic social support and relatively rare post-traumatic negative events may also serve as protective factors that will aid recovery from trauma [54].

COMBAT AND OPERATIONAL STRESS CONTROL (COSC) PROGRAMS IN MILITARY PERSONNEL

In our opinion, programs for the prevention and control of combat stress among military personnel are more effectively implemented in the Armed Forces of the United States, Great Britain, and Israel; other countries are developing similar activities based on these programs.

Trauma Risk Management (TRiM) is a peer-support program that aims to promote help-seeking military personnel in the aftermath of traumatic events, developed by the UK Royal Navy [55]. This program reflects a peer-led, occupational mental health support process that aims to identify and assist U.K. military personnel with persistent mental ill health related to potentially traumatic events [56]. TRiM seeks to modify attitudes about PTSD, stress, and help-seeking and trains military personnel to identify at-risk individuals and refer them for early intervention.

The use of TRiM may assist in increasing the psychological resilience of military personnel through the facilitation of social support; this may have particular utility during operational deployments [57].

The Israel Defense Forces developed YaHaLOM training to teach service members how to manage ASRs in team members [58] and then adapted into ICOVER by the U.S. Army. YaHaLOM is a novel, rapid, peer-based intervention specifically designed for use amid a high-stress event.

The analysis of scientific sources made it possible to determine that the most effective system for the prevention and control of combat stress among military personnel exists in the US Army. Let's consider this system in more detail. There is a specific terminological apparatus for defining terms related to combat stress that is used by mental health professionals in the US military. They are set out in various legal documents that regulate the professional activities of these specialists: COSC programs are set out in Field Manual 4-02.51 "Combat and Operational Stress Control" and 6-22.5 "Combat and Operational Stress Control Manual for Leaders and Soldiers" [45,59].

Thus, the control of combat and operational stress in the US Army is defined as the developed programs and activities of military leaders aimed at preventing, identifying, and managing dangerous behavior and combat stress reactions that may occur in military personnel [59]. The objectives of the COSC program are optimization of task performance; maintaining combat power; preventing the harmful effects of combat stress reactions on the physical, psychological, intellectual, and social health of military personnel or minimizing these effects; prompt return of soldiers to duty [60].

Also, one of the main tasks of the COSC is to increase unit cohesion and combat capability in a highly stressful military environment and to maximize post-traumatic growth [48]. COSC includes such activities as in-depth medical examination (screening) and psychodiagnostic of recruits; long-term observation of the passage of service, especially before, during, and after combat deployment; ongoing monitoring and consultation of mental health personnel from the US home base to the combat deployment area [61].

In the past, when US military personnel participated in operations in Korea and Vietnam, the consequences of the negative impact of combat stress led to almost half of the psychogenic losses on the battlefield, depending on the complexity of the conditions [47]. Although the level of acute (combat) stress reactions remained high in the wars of the 21st century, losses were significantly reduced. This was due to the introduction of COSC programs into the functioning of military units. According to American mental health professionals, in modern wars, military leaders can expect 95% of military personnel with ASRs should return to combat missions [47]. COSC is effective when it comes not only to military personnel but also to their training and support systems, including meaningful interpersonal relationships, families, and external resources. COSC aims to identify members of the armed forces and their families, as well as US Army civilians who may need assistance due to challenges associated with participating in combat deployments, and to ensure that they are better prepared, stable, and reliable at all stages accomplishment of combat missions. If we consider the personal level of a soldier, then the goal of COSC is to improve the readiness of each soldier and the unit as a whole to perform a combat mission. This can be achieved by: improving adaptive stress responses and preventing unproductive coping strategies; helping military personnel control combat stress responses; helping soldiers with behavioral problems [6].

Overall, the US Army's COSC is one of 10 medical systems active during pre-combat, on the battlefield, and at the end of a mission. Five professional disciplines in mental health and two additional ones are directed to the implementation of COSC. Professional disciplines include social work, clinical psychology, psychiatry, occupational therapy, and psychiatric nursing. Additional disciplines include mental health and vocational rehabilitation.

An analysis of the COSC programs of different armies of NATO partner countries in the field of international security assistance showed that they are similar in terms of organizational principles, main goals, and tasks. However, these programs differ structurally from the US Army COSC and have their own characteristics depending on the conditions of the missions in which the military personnel take part and the performance of combat missions. Such a comparison of COSC programs was made during a mission in Afghanistan among five NATO partner countries: the armed forces of Australia, Canada, the UK, the Netherlands, and the USA [8]. This allowed the authors to identify and compare organizational structures and key practices in providing mental health care and support to military personnel, identify issues, and illustrate new developments in this area.

The main comparative themes of the COSC programs were: education, prevention, early detection, intervention (care), and follow-up (support) in the field of mental health. The main method of organizing support for the mental health of servicemen was training (psycho-prophylaxis) and monitoring their mental state. The educational goal was to enhance the mental stability of individual military personnel while providing a range of mental health services. All mental health officials from these five countries have waived the need for a standard psychological debriefing after critical incidents (military deaths and large numbers of wounded). Instead, these specialists monitored the mental state of military personnel and their commanders during mandatory post-combat checkups and interviews [35].

To organize psychological support for military personnel, specialized mental health units were deployed near the line of combat, the main purpose of which was the early identification, assistance, and early return to normal activities of such military personnel in the units [62]. All countries have deployed mental health support teams made up of a variety of professionals, including psychiatrists, psychologists, social workers, nurses, and priests [63]. There was no consensus on the distribution of mental health disciplines in the war zone.

All countries, except the United States, organized psychological decompression for personnel in temporary deployment elsewhere (outside the combat zone, but in areas of temporary deployment of units) within a few days after the completion of combat deployment. Its main goal was to recognize faces with signs of combat stress reactions, to provide them with assistance, psychological support, and preparation for sending them to permanent deployment points (home). The US Army conducted intra-garrison decompression or reintegration training directly in the US [8]. But psychological decompression had a fairly comparable infrastructure in the field of psychiatric and psychological care.

Common concerns across countries included perceived stigma (unwillingness or fear of military personnel to seek help from mental health professionals), barriers to mental health care, and the need to increase awareness and acceptance of mental health issues among military personnel [64].

In addition to psychological support, modern preventive psychiatric treatment was included in all COSC programs, including a positive approach to strengthening mental stability. There has also been an emphasis on building self-regulatory skills, empowering military personnel, and several other innovations well integrated into the military context [63]. An important innovation in the operational mental health support of military personnel was the recognition of the role of social leadership and the need to increase support from colleagues.

However, not all researchers are positive about the introduction of COSC programs to prevent the development of mental disorders in military personnel that occur during and after combat deployment. Maglione et al. believe that although COSC interventions may play a valuable role in decreasing stress, decreasing absenteeism, and enabling a return to duty, a systematic review of studies that included a control/comparison group found little evidence that COSC is effective in preventing PTSD or decreasing PTSD symptom scores in military personnel [65].

CONCLUSIONS

One of the most important directions in the development of military psychology is the study of the problem of stress. The conservation of resource theory by S. Hobfoll, in our opinion, most fully and reasonably explains the genesis of combat stress that occurs in military personnel during activities in extreme conditions. The main postulate of this theory is that stress occurs when a person's central or key resources (health, well-being, family, self-esteem, and a sense of purpose and meaning in life) are threatened with loss, lost, or there is a failure to gain key resources following significant effort. At its core, the conservation of resource theory is a motivational theory that explains much of human behavior in terms of the evolutionary need to obtain and conserve resources in order to survive.

It was revealed that during the fighting, almost all servicemen experience combat stress. Combat stress is the process of the influence of combat situation factors on a soldier, accompanied by a decrease in the level of psychological safety of personality and the appearance of non-specific preclinical psychological manifestations, which together are presented by the concept of "combat psychological trauma of personality" or reach specific nosological symptoms of mental disorders, united in the concept of "combat mental trauma".

To prevent the occurrence and development of combat stress, it is necessary to develop and implement a system for the prevention and control of combat stress in military personnel. Such a program should contain psychological work activities carried out at three stages: preparatory (before performing combat missions), the stage of direct performance of tasks in the combat zone, and the final stage (after completing tasks upon returning to permanent deployment points).

Conflicts of interest and sources of funding

The authors declare no conflict of interest. No financial support was received from any governmental institution, economic or non-governmental organization.

Authors' contribution

Conceptualization and project management, I.P.; research, YaM., O.K and S.V.; methodology, V.V.; formal analysis, N.V.; software, L.B.; writing – original draft preparation, V.K. and S.M. All authors read and agreed to the published version of the manuscript.

Abstract: *Mental disorders clearly are among the major challenges of global health causing many concerns for health systems, health experts, and health policy makers. The present study was conducted to evaluate the mental health program in comprehensive health centers and health houses under the coverage of the Ilam University of Medical Sciences in the West of Iran. The present study was conducted based on the reports obtained from the mental health program in 2019. The data were recorded into registration and evaluation forms of mental disorders with the codes 102-19-03 and 102-19-01 and then entered into the Excel software. The prevalence per 100 and 100,000 people, as well as their 95% confidence intervals, were calculated using Formula 1 ROUND (Number of cases*100000/population) and Formula 2 ROUND (Prevalence ±1.96*SQRT (Prevalence *(1-Prevalence)/population). The results showed that the prevalence of depression was 19,100 [95% CI: 18999-19201] 19100), and the prevalence of anxiety was 304,66 [95% CI: 20348-30584] per 100,000 population. The highest prevalence among mental disorders was related to depression and anxiety. Considering the high average score of mental health status in people over 65 years old, it is necessary to implement measures and interventions to improve these individuals' mental conditions and upgrade their mental health.*

Keywords: *Spatial analysis; Ilam province; Mental health; Iran*

INTRODUCTION

According to the definition provided by the World Health Organization (WHO), mental health is "a health status that turns one's potential talents into reality, enabling people to cope with routine life tensions, accomplish valuable work, and upgrade their social participation" [1]. Mental health is an important component for evaluating the health status of a population and can be evaluated using various indicators [2]. In other words, the concept of mental health falls under the general concept of health and refers to all the methods and measures used to prevent people from developing mental disorders, as well as for the treatment and rehabilitation of affected individuals. Psychologists believe that mental health can be affected by individual characteristics, mental and environmental burdens, economic, social, and familial status, failure to achieve life goals, and lack of motivation [3]. Industrialization of countries, the growth of urbanization, migration to cities, etc. are phenomena that are associated with numerous troubles, including psychological and social problems. For this reason, mental health and mental disorders are considered top priorities in today's world. The high prevalence of mental disorders and their associated morbidities render them an immediate health priority [4].

Excessive attention to physical health problems (such as infectious and contagious diseases) has caused mental health to receive less priority in many countries around the world, including its social and spiritual aspects, which have been overlooked in most cases [5]. Statistics on the global burden of mental illnesses highlight the need to pay attention to these aspects more than ever. In parallel with the estimation of the WHO, Harvard University and the World Bank declared that mental disorders were responsible for about 13% of the total burden of diseases in 2006, which was predicted to reach 15% by 2020. The rate of morbidities caused by these disorders has been reported beyond 33% [6]. In Iran, mental health disorders account for 14.5% of the total burden of diseases, and after traffic accidents, they share the second rank with cardiovascular diseases. In women, depression claims the first place of disease burden, while in men, addiction is considered the third cause of disease burden[7]. According to studies in Iran on individuals older than 15 years old, the prevalence of mental disorders has been 25.9% in women and 14.9% in men, and it was reported that overall, 21% of people suffered from some sort of mental problems. Some studies have assessed the prevalence of mental disorders in Ilam province{8]. In a population-based study by Visani et al. [9], the prevalence of DSM-IV mental disorders in both genders was investigated in the urban areas of Ilam province. Out of 763 participants aged 15 years and older in the recent study, 25.8% showed symptoms of mental distress, and the prevalence of mental disorders was reported to be 20.9% in men and 29.8% in women. Also, the prevalence of anxiety, major depressive disorder (MDD), and obsessive-compulsive disorder was higher in women than in men (23.6% vs. 18.2%; 22.7% vs. 17.4%; 13.9% vs. 10%, respectively). In women, the prevalence of phobia was reported as 10.4%.

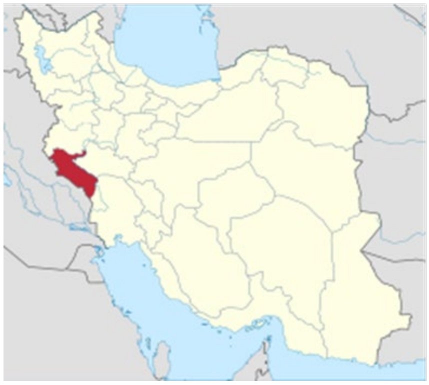
Studying mental health status can provide managers and decision-makers of organizations with valuable information for planning educational, therapeutic, and preventive measures to reduce the incidence of these diseases in society. Such information can be obtained by monitoring the mental health status of people in different societies [5].

Assessment and monitoring of mental disorders in the country and in Ilam province can help better understand the condition of mental health and public health in society, which is an important and influential factor affecting social productivity and wealth creation. Therefore, researchers here aimed to investigate the mental health status of the urban population of Ilam using the data recorded in the registration and assessment forms designed for mental disorders. Furthermore, we evaluated the mental health program performed in comprehensive health centers and health houses covered by the Ilam University of Medical Sciences in the West of Iran.

MATERIALS AND METHODS

The present cross-sectional study was conducted on the basis of the reports derived from the mental health program in Ilam province in 2020. According to the statistics announced in 2021, Ilam province harbors a population of over 630,000 people living in ten cities: Ilam, Ivan, Chardavl, Sirvan, Malekshahi, Mehran, Abdanan, Dehloran, Badreh, and Darrehshahr (Figure 1).

Figure 1: The geographical location of Ilam province



This study was conducted to assess the mental health program implemented in the comprehensive health centers and health houses affiliated with the Ilam University of Medical Sciences in 2019. The study was approved by the institutional ethics committee under the code IR.MEDILAM.REC.1399.266. The data were gathered by reviewing registration and evaluation forms for mental disorders with the codes 102-19-03 and 102-19-01 in all ten cities of Ilam province. Then based on the population of each city in 2021, the prevalence of mental disorders was calculated in 100 and 100,000 people.

Analytic Method

After collection, the data of each city were entered into Microsoft Excel software, and formulas 1 and 2 were used to calculate the prevalence of mental disorders (with 95% CIs) in 100 and 100,000 people.

Formula 1: ROUND (Number of cases*100000/population)

Formula 2: ROUND Prevalence ±1.96*SQRT (Prevalence *(1-Prevalence)/population)

Also, to determine the geographical distribution of mental disorders in the cities of Ilam province, the commands of spatial analysis in the STATA 11 software (Stata Corp. LLC College Station, Texas, USA) were used.

RESULTS

The results showed that in Ilam province, the prevalence of depression was 19100 (95% CI: 18999-19201), and the prevalence of anxiety was 30466 (95% CI: 20348-30584) per 100,000 people. According to the results, the highest prevalence among mental disorders was related to depression and anxiety.

The highest rate of depression belonged to Ilam (20300, 95% CI: 20137-20463) and Malekshahi (21836, 95% I: 21297-22375) cities, while the lowest rate of depression was reported in

Sirvan (16292, 95% CI: 15691-16897) and Badreh (17299, 95% CI: 16706-17892).

Also, the highest rates of anxiety were recorded in the cities of Abdanan (22298, 95% CI: 21922-22674), Ivan (22559, 95% CI: 22228-22970), and Ilam (21200, 95% CI: 210135-21365). On the other hand, the cities of Sirvan (16769, 95% CI: 16184-17404), Chardavl (16499, 95% CI: 16228-16770), and Darrehshahr (19099, 95% CI: 17790-18408) had the lowest rate of anxiety (Table 1).

Table 1: The prevalence of depression and anxiety in the population of Ilam province per 100,000 people in separate cities

Location	Population	Major Depressive Disorder		Anxiety Disorder	
		Prevalence		Prevalence	
		Number of cases	Rate per 100,000 (CI 95%)	Number of cases	Rate per 100,000 (CI 95%)
Ilam	235144	47734	21200(210135-21365)	49850	20300(20137-20463)
Abdanan	46977	9630	22298(21922-22674)	10475	20499(20134-20463)
Ivan	48833	10236	22559(22228-22970)	11036	20961(20600-21322)
Mehran	27506	5281	22402(21909-22895)	6162	19199(18734-19664)
Badreh	15614	2701	17299(16706-17892)	2701	17299(16706-17892)
Dehloran	66339	13135	18900(18602-19198)	12538	19800(19497-20103)
Darrehshahr	59551	10838	18099(17790-18408)	10778	18200(17890-18510)
Shirvan	14404	2347	16796(16184-17404)	2419	1294(15691-16897)
Chardavl	72167	12412	16499(16228-16770)	11907	17199(16924-17474)
Malekshahi	22587	4932	17196(16704-17668)	3884	21836(21297-22375)
Total	580148	110808	30466(20348-30584)	176750	19100(18999-19201)

Regarding age distribution, the results showed that the highest prevalence of depression (29%), anxiety (35.5%), and psychotic disorder (22.6%) was observed in people over 65 years of age. The psychological disorders of mania (6.3%) and obsessive-compulsive disorder (13.3%) were more commonly observed in the age group of 15-24 years compared to other age groups.

Regarding the gender distribution of mental disorders, it was noticed that depression (20.3% vs. 22.7%), mania (2.6% vs. 4.7%), anxiety (23.6% vs. 32.18%), obsessive-compulsive disorder (10% vs. 13.79%), phobia (10.4% vs. 5%), and psychotic disorder (6.17% vs. 2.4%) were more frequent in women than in men (Table 2).

Table 2: The prevalence of mental disorders in Ilam province in various age groups and genders

Age groups/gender	Depression	Mania	Anxiety	OCD*	Phobia	Psychotic

**OCD – Obsessive-compulsive disorder*

The results of the spatial analysis regarding the geographical distribution of mental disorders in Ilam province showed that depression, anxiety, and mania were more commonly observed in the northern compared to southern regions of the province, showing the highest prevalence in Ivan City. Also, panic disorder was more prevalent in southern cities of the province (Abdanan and Dehloran) than in other cities (Figure 2).

DISCUSSION

The results of the present study showed that the highest prevalence of depression, anxiety, and psychotic disorders was observed in people over 65 years old. In this study, age showed a direct and significant correlation with having unsatisfactory mental health, indicating the importance of advancing age in the development of mental health problems such as depression, anxiety, and psychotic disorders. In other words, the incidence of mental health disorders increased with age, contradicting the findings of Heidari et al. [10] and Jafari et al. [11]. In recent studies, higher age was reported to be significantly associated with more favorable mental health. Other studies; however, have reported a significant relationship between mental health and advancing age, including a report by Visani et al. [12]. In another study, Noorbala et al. [13] noted that with increasing age, the likelihood of the development of mental disorders increased so the highest prevalence (49.9%) was related to people over the age of 65 years. Among the reasons for the higher prevalence of mental health disorders in older people can be retirement, menopause, loneliness-associated anxiety, and biological alterations. The results of these studies are generally consistent with our findings; nevertheless, some discrepancies can be explained by differences in the assessment tools employed and the age spectra of the studied populations.

The results of this study showed that the highest prevalence of panic disorder and obsessive-compulsive disorder was related to the age group of 15-24 years. Mental disorders in teenagers and young adults exacerbate the predicted future burden of diseases and adversely affect numerous life aspects, including educational performance, employment, income, personal relationships, and social participation, as well as workforce [14]. In a study in Brazil conducted on individuals aged 18 years and older, it was shown that younger people were more vulnerable to mental problems [15]. In another study in Iran, Shirzadi et al. [16] declared a higher prevalence of these disorders in people aged 41 years or older compared to 18-40-year-old individuals.

Also, the results of the present study revealed a lower prevalence of depression and anxiety in women than in men. In a study, Falahzadeh and Momayezi [17], who investigated the prevalence of depression, anxiety, and stress in Yazd city of Iran, noted that depression, anxiety, and stress were more prevalent in women than in men, and this difference was statistically significant for anxiety (P=0.01) and stress (P=0.02), which was not consistent with our observation. We also noticed a higher prevalence of obsessive-compulsive disorders, phobia, and psychotic disorders in women compared to men, which was in agreement with the reports of Pendrez et al. [18], Kesler et al. [19], and Chang et al. [20]. The higher prevalence of mental disorders in women compared to men can be attributed to biological factors, gender-related differences, environmental and occupational stress, as well as limited sources of satisfaction and social participation of females.

Although in the present study, a significant portion of the urban population declared that they had unsatisfactory mental health conditions, this may not exactly match the clinical definition of adverse mental health. Therefore, the results of such subjective studies should not be regarded as a basis for judgment about the true condition of the mental health of respondents. Nevertheless, one should admit that a ratio of people, especially among women, suffer from some degree of mental health disorders. In this regard, the key measures that can be taken may be to initially achieve a correct understanding of the issue and then to implement comprehensive interventions for monitoring populations as large as possible, especially among vulnerable groups. Numerous viable strategies are available to maintain and improve public health. For example, unemployment has been pointed out as an important factor contributing to the development of mental health disorders [21]. So, an important intervention that governments can employ is to create more jobs, especially for youth, and to improve people's livelihoods as much as possible. Also, another effective measure for improving mental health is to remove the sources of distress, psychological pressure, and unnecessary tensions, which can be achieved with the help of mass media by nurturing a comfortable atmosphere. Moreover, the establishment of psychological counseling clinics can be among low-cost and beneficial measures to cover a large population, including young people, middle-aged, and elderly people, so that they can amend and improve their mental health.

CONCLUSIONS

The results of this study affirmed a relatively high prevalence of suspected mental health problems among people over 65 years of age, which is an alarming call,

requiring authorities and researchers to pay more attention to this issue and to identify and modify the factors affecting the mental health of these people. A unique observation in this study was the lower prevalence of anxiety and depression in women than in men. Also, we noticed that panic disorder and obsessive-compulsive disorder were most prevalent in the age group of 15-24 years. A reduction in the prevalence of mental disorders can enhance social liveliness. In this regard, increasing people's awareness of ways to reduce mental disorders, expanding psychological counseling centers across the city, the establishment of counseling phone lines, residing counselors and psychologists in public places such as mosques, expansion of parks and enjoyable environments, equipping parks with sports devices, and finally, encouraging people to use these services can help reduce depression and anxiety in society.

Abstract: *Background: Adolescence is a complex and sensitive period, and learning nutritional concepts during this period is very important. The purpose of the present study is to determine the predictive power of the theory of planned behavior on the behavioral intention of healthy eating in adolescents. Methods: 400 first-grade female students of Bandar Anzali participated in this descriptive-correlational study. Among the first secondary schools of this city, two schools were randomly selected and sampled by census method. The data collection tool was the healthy eating behavior questionnaire based on the theory of planned behavior, which included two sections of demographic information and the constructs of the theory of planned behavior, which were checked and confirmed with the content validity ratio, content validity index, and alpha coefficient. Data were analyzed using SPSS version 22 software. Results: Linear regression analysis showed that a total of 34% of the variance of healthy eating behavior intention is predicted by the constructs of perceived behavioral control and attitude. Conclusion: Considering the high predictive power of the theory of planned behavior in the field of healthy eating behavior, educational interventions based on it and centered on predictive structures are suggested.*

Keywords: *theory of planned behavior, healthy eating, adolescents*

INTRODUCTION

Non-communicable diseases (such as cardiovascular diseases, diabetes, cancer, high blood pressure, obesity, etc.) are the main cause of death worldwide [1]. Due to the increase in the death rate caused by these diseases, especially in developing countries, the World Health Organization (WHO) declared non-communicable diseases among the health priorities in developing countries two decades ago [2]. Iran, as an example of a middle-income country, accounted for 83.5% of all deaths and 78.1% of the total disease burden in 2019 due to non-communicable diseases [3-5].

The role of nutrition as the main cause of these diseases has been proven correctly [6]. In this regard, especially, the unhealthy eating behavior of teenagers is worrying [7]. Rapid growth, and changes in body composition, physiology, and endocrine system accelerate nutritional needs and increase the risk of malnutrition in this group [8]. Adolescents have more decision-making power and independence than children and are heavily influenced by friends, people around them, the environment, and various advertisements, and they turn to foods with an attractive and seductive appearance but lacking in nutritional value, many ready-made foods and snacks are among these materials [9]. Most of them do not consume enough fruits and vegetables, instead, they consume high-fat, energy-rich, and nutrient-poor foods [10].

According to the 2019 GSHS (Global School-based Student Health Survey), almost half of the countries reported that 10-30% of students aged 13-15 did not eat any fruit, a quarter reported that 10-30% of students did not eat any vegetables, and almost 70% of countries reported that at least half of their students eat junk food on a weekly basis and all countries have found that one in five students consumes carbonated drinks at least once a day [11].

Among Iranian teenagers, high consumption of junk foods and unhealthy snacks, not eating breakfast, and low consumption of fruits, vegetables, whole grains, and dairy products have been commonly reported [12] and this will cause them to develop chronic diseases in the future, especially girls who are considered as the future mothers and their eating behavior and learning nutritional concepts affect their own health and that of their children and families [13,14].

Modifying eating habits and behaviors during childhood and adolescence can prevent the occurrence of many non-communicable diseases in adulthood [15]. On the other hand, the future of any country depends on how it takes care of its children and teenagers. If action is taken to meet their health needs, the possibility that the adults of that society will have a healthy and valuable life pattern in the future will increase [16]. On the other hand, the future of any country depends on how it takes care of its children and teenagers. If action is taken to meet their health needs, the possibility that the adults of that society will have a healthy and valuable life pattern in the future will increase [17].

Studies show that the most effective educational programs are based on theory-based approaches that are rooted in behavior change patterns, and the "theory of planned behavior" is one of the well-known ones [18]. According to this theory, attitude, subjective norms, and perceived behavioral control affect the intention to perform a behavior [19]. A person's attitude is a favorable or unfavorable evaluation of behavior formed through past experiences.

Subjective norms refer to the social pressures perceived by the person who agrees or disagrees with the behavior and the media, family, and friends play a role in it. Finally, perceived behavioral control is a person's belief about how easy or difficult it is to perform a certain behavior [20]. According to the explanations provided, the present study was conducted with the aim of determining the predictive power of the theory of planned behavior on the behavioral intention of healthy eating in adolescents.

MATERIALS AND METHODS

This is a descriptive-correlational study, which was conducted in 2022. The research population was 400 first-grade high school girls in Bandar Anzali. From among the first high school girls in this city, two schools were randomly selected and sampled by census method. Inclusion criteria included: students' willingness to participate in research, lack of a special diet and not suffering from chronic diseases, and exclusion criteria were unwillingness to participate and continued cooperation by students.

The study was initiated with the permission of the ethics committee of Iran University of Medical Sciences and the necessary coordination with the education organization of Bandar Anzali city, the principals and officials of the relevant schools, and the informed consent of the students. The data collection tool was the healthy eating behavior questionnaire based on the theory of planned behavior [21].

This questionnaire includes two sections of demographic information and constructs of the theory of planned behavior. The first part of this questionnaire included 8 items related to demographic characteristics, including student age, height, weight, parent’s education, parent's occupation, and household size. The second part or constructs of the theory of planned behavior consists of 32 items, and the third part, or food behavior part includes 7 items, based on the 5-point Likert scale each item, as (strongly disagree, disagree, no idea, agree, strongly agree) with a minimum and maximum score of 1 to 5. The second part of the questionnaire includes attitudes toward behavior with 12 items with an achievable score range of 12 to 60, 13 items for subjective norm with an achievable score range of 13 to 65, perceived behavioral control with 7 items with an achievable score range of 7 to 35, behavioral intention with 6 items with an achievable score range of 6 to 30. In the present study, due to the limitation of answer options for items in the questionnaire, which were 4-point Likert, the questionnaire was re-validated and reliable.

To assess the validity, content validity was used, so that the questionnaire was given to 10 health and nutrition experts, and its validity was confirmed with a content validity ratio (CVR) of 0.81 and a content validity index (CVI) of 0.8. To assess the reliability, Cronbach's alpha test method was used. For this purpose, a questionnaire was given to 20 female high school students. Cronbach's alpha coefficient was 0.85 for the attitude construct, 0.75 for the subjective norm construct, and 0.71 for the perceived behavioral control construct, 0.76 for the behavioral intention construct. Data analysis was done by SPSS software version 24.

RESULTS

In this study, the mean age of students was 14.9 ± 0.78 years. Their mean height and weight were 159.7 ±10.7 and 54.7± 1.4, respectively, and the household size was 4.1 ± 0.8. In terms of employment, the highest frequency was for fathers (45%) as self-employment and 86% of mothers were housewives. In terms of education, 42% of fathers and 45% of mothers were at the level of high school and high school diploma, each of which with the highest percentage of frequency. The mean, standard deviation, and range of obtainable scores for each construct of the theory of planned behavior in the studied students can be seen in Table 1.

Table 1: Mean, standard deviation, and range of obtainable scores for each of the constructs of the theory of planned behavior in the studied students

Variable	Mean ± SD‣	Rang of attainable score
attitude	40 ± 6.21	12-60
subjective norms	38.9 ± 6.44	13-65
perceived behavioral control	24.06 ± 6.44	7-35
behavioral intention	25.47 ± 9.21	6-30

‣ *Standard Deviation*

Table 2 shows the results of Pearson correlation between the constructs of the theory of planned behavior that there is a direct and significant correlation between all constructs (attitude, subjective norm, and perceived behavioral control) with the intention of eating behavior (P<0.001). The construct of perceived behavioral control has the highest correlation with the intention of eating behavior (r=0.302).

The linear regression analysis in Table 3 showed that a total of 34% of the variance of the intention of healthy eating behavior in the studied students is predicted by the constructs of perceived behavioral control and attitude, and perceived behavioral control is the strongest construct related to the intention of eating behavior in this study.

Table 2: Correlation between the constructs of the theory of planned behavior

Variable	Attitude	Subjective norms	Perceived behavioral control	Behavioral intention
attitude	1			
subjective norms	0.191	1		
perceived behavioral control	0.276	0.145	1	
behavioral intention	0.182	0.255	0.302	1

Model		B	Std. Error	Beta	sig
1	(Constant)	5.231	3.424	_	0.127
	attitude	0.157	0.070	0.113	0.024
	subjective norms	0.119	0.085	0.088	0.163
	perceived behavioral control	0.371	0.103	0.230	0.000

a. Dependent Variable: Intention of food behavior; b. R2 = 0.34

DISCUSSION

The present study was conducted with the aim of determining the predictive power of the theory of planned behavior on the behavioral intention of healthy eating in adolescents. The result of the study shows that a total of 34% of the variance of healthy eating behavior intention in the studied students is predicted by the constructs of perceived behavioral control and attitude, and perceived behavioral control is the first and strongest construct related to behavioral intention, which is consistent with studies predicting healthy eating in Danish adolescents [22] and the results of the study by Seo et al in Seoul, which implies a significant relationship between behavioral intention and perceived behavioral control construct [23]. It is also consistent with the findings by Yarmohammadi et al. [24] and Dunn et al. [25] on junk food consumption based on the theory of planned behavior. However, it is not consistent with the findings of Ickes et al. [26] on beverage consumption and the findings of Gholami et al. [27] on fruit and vegetable consumption. Perceived behavioral control may not predict behavior when a person has little information or the resources available to the person change and when new elements such as eating habits are added to the situation [28, 29].

The second construct predicting the intention of healthy eating behavior in this study is the attitude, which is consistent with the results of the study by Mousavi et al. [30] concerning beverage consumption and the study by Gronhoj et al. [22] regarding the prediction of healthy eating behavior and the study by Mamun et al. [31] on the determinants of healthy eating. Attitude shows an individual’s general feeling about the desirability or undesirability of something, and sometimes people's attitude during life as well as sufficient awareness and knowledge, which is a prerequisite for attitude change, leads to the intention of performing the desired behavior in the future [27]. Therefore, the attitude that originates from feelings and internal factors can affect his eating behavior by increasing his information and experiences concerning nutrition.

In this study, the subjective norm is not a predictor of eating behavior intention, which is similar to the finding by Ismawati et al. [32] on the application of the theory of planned behavior in the intention of healthy eating in Malaysia and the study of Brouwer et al. [33] related to healthy eating behavior prediction and finding by Dehdari et al. [34] regarding the consumption of unhealthy foods. However, it is inconsistent with the findings of Khorasani et al. [35] on unhealthy food consumption and White et al. [36] regarding intention to consume low-fat food. The reason for this inconsistency can be the difference in the gender of the participants, in the study of Dehdari et al. [34], as in the present study, the target group is girls, and in the study of Khorasani et al. [35], boys are the target group. On the other hand, diverse food cultures and customs in Iran and other countries of the world can be the reason for the discrepancy of these studies. The diversity and complexities of health behaviors in different groups and in different conditions can lead to the necessity of planning to use the appropriate theories and structures to achieve success in interventions in health education and health promotion.

CONCLUSIONS

Perceived behavioral control and attitude are among the factors predicting on the behavioral intention of healthy eating in the studied students. The research limitation in the present study was the use of self-reporting, and it is necessary to carry out educational interventions based on the "theory of planned behavior" with emphasis on the two predictive constructs mentioned.

Conflicts of interest and sources of funding

The personal interests of the authors were not related to the results of this research. The authors declare that they have no competing interests. This study did not receive any grant from funding agencies.

Authors' contribution

All authors were responsible for the study. EA, MM, and TD were accountable for the study Conceptualization and led the writing of the paper. BI conducted the Literature review and assisted in writing the paper. MM and OS performed the Statistical analysis, assisted in interpreting the data, and wrote the paper. OS, FSI, and EA assisted with the interpretation of the results and drafting of programmatic Implications. FB and MM were responsible for data collection and coordination of the study. TD co-led the conceptualization, supervised all aspects of writing the paper, and provided extensive comments on the manuscript. All the authors have read and approved the final manuscript.

Acknowledgments

The cooperation of all the students and heads and officials of the Iran University of Medical Sciences and Education Organization of Bandar Anzali and the officials of the studied schools is highly appreciated.

Ethics approval and consent to participate

This article is taken from the approved research project of Iran University of Medical Sciences with ethics code number: 1401.886 IR.IUMS.REC. Informed consent was obtained from all individual participants included in the study before conducting.

Consent to publish

All participants consented verbally to the publication of the interview data.
